About This Edition

STUDIES ON HYSTERIA
(1893-1895)

Intentionally left blank

PREFACE TO THE FIRST EDITION

In 1893 we published a 'Preliminary Communication'¹ on a new method of examining and treating hysterical phenomena. To this we added as concisely as possible the theoretical conclusions at which we had arrived. We are here reprinting this 'Preliminary Communication' to serve as the thesis which it is our purpose to illustrate and prove.

We have appended to it a series of case histories, the selection of which could not unfortunately be determined on purely scientific grounds. Our experience is derived from private practice in an educated and literate social class, and the subject matter with which we deal often touches upon our patients' most intimate lives and histories. It would be a grave breach of confidence to publish material of this kind, with the risk of the patients being recognized and their acquaintances becoming informed of facts which were confided only to the physician. It has therefore been impossible for us to make use of some of the most instructive and convincing of our observations. This of course applies especially to all those cases in which sexual and marital relations play an important aetiological part. Thus it comes about that we are only able to produce very incomplete evidence in favour of our view that sexuality seems to play a principal part in the pathogenesis of hysteria as a source of psychical traumas and as a motive for 'defence' - that is, for repressing ideas from consciousness. It is precisely observations of a markedly sexual nature that we have been obliged to leave unpublished.

The case histories are followed by a number of theoretical reflections, and in a final chapter on therapeutics the technique of the 'cathartic method' is propounded, just as it has grown up under the hands of the neurologist.

If at some points divergent and indeed contradictory opinions are expressed, this is not to be regarded as evidence of any fluctuation in our views. It arises from the natural and justifiable differences between the opinions of two observers who are agreed upon the facts and their basic reading of them, but who are not invariably at one in their interpretations and conjectures.

J. BREUER, S. FREUD

April 1895

PREFACE TO THE SECOND EDITION

The interest which, to an ever-increasing degree, is being directed to psycho-analysis seems now to be extending to these *Studies on Hysteria*. The publisher desires to bring out a new edition of the book, which is at present out of print. It appears now in a reprint, without any alterations, though the opinions and methods which were put forward in the first edition have since undergone far-reaching and profound developments. So far as I personally am concerned, I have since that time had no active dealings with the subject; I have had no part in its important development and I could add nothing fresh to what was written in 1895. So I have been able to do no more than express a wish that my two contributions to the volume should be reprinted without alteration.

BREUER

As regards my share of the book, too, the only possible decision has been that the text of the first edition shall be reprinted without alteration. The developments and changes in my views during the course of thirteen years of work have been too far-reaching for it to be possible to attach them to my earlier exposition without entirely destroying its essential character. Nor have I any reason for wishing to eliminate this evidence of my initial views. Even to-day I regard them not as errors but as valuable first approximations to knowledge which could only be fully acquired after long and continuous efforts. The attentive reader will be able to detect in the present book the germs of all that has since been added to the theory of catharsis: for instance, the part played by psychosexual factors and infantilism, the importance of dreams and of unconscious symbolism. And I can give no better advice to any one interested in the development of catharsis into psycho-analysis than to begin with *Studies on Hysteria* and thus follow the path which I myself have trodden.

FREUD

PRELIMINARY COMMUNICATION
(1893)

(BREUER AND FREUD)

I

ON THE PSYCHICAL MECHANISM OF HYSTERICAL PHENOMENA:
PRELIMINARY COMMUNICATION (1893)

(BREUER AND FREUD)

I

A chance observation has led us, over a number of years, to investigate a great variety of different forms and symptoms of hysteria, with a view to discovering their precipitating cause - the event which provoked the first occurrence, often many years earlier, of the phenomenon in question. In the great majority of cases it is not possible to establish the point of origin by a simple interrogation of the patient, however thoroughly it may be carried out. This is in part because what is in question is often some experience which the patient dislikes discussing; but principally because he is genuinely unable to recollect it and often has no suspicion of the causal connection between the precipitating event and the pathological phenomenon. As a rule it is necessary to hypnotize the patient and to arouse his memories under hypnosis of the time at which the symptom made its first appearance; when this has been done, it becomes possible to demonstrate the connection in the clearest and most convincing fashion.

This method of examination has in a large number of cases produced results which seem to be of value alike from a theoretical and a practical point of view.

They are valuable theoretically because they have taught us that external events determine the pathology of hysteria to an extent far greater than is known and recognized. It is of course obvious that in cases of 'traumatic' hysteria what provokes the symptoms is the accident. The causal connection is equally evident in hysterical attacks when it is possible to gather from the patient's utterances that in each attack he is hallucinating the same event which provoked the first one. The situation is more obscure in the case of other phenomena.

Our experiences have shown us, however, that the most various symptoms, which are ostensibly spontaneous and, as one might say, idiopathic products of hysteria, are just as strictly related to the precipitating trauma as the phenomena to which we have just alluded and which exhibit the connection quite clearly. The symptoms which we have been able to trace back to precipitating factors of this sort include neuralgias and anaesthesias of very various kinds, many of which had persisted for years, contractures and paralyses, hysterical attacks and epileptic convulsions, which every observer regarded as true epilepsy, *petit mal* and disorders in the nature of *tic*, chronic vomiting and anorexia, carried to the pitch of rejection of all nourishment, various forms of disturbance of vision, constantly recurrent visual hallucinations, etc. The disproportion between the many years' duration of the hysterical symptom and the single occurrence which provoked it is what we are accustomed invariably to find in traumatic neuroses. Quite frequently it is some event in childhood that sets up a more or less severe symptom which persists during the years that follow.

The connection is often so clear that it is quite evident how it was that the precipitating event produced this particular phenomenon rather than any other. In that case the symptom has quite obviously been determined by the precipitating cause. We may take as a very commonplace instance a painful emotion arising during a meal but suppressed at the time, and the producing nausea and vomiting which persists for months in the form of hysterical vomiting. A girl, watching beside a sick-bed in a torment of anxiety, fell into a twilight state and had a terrifying hallucination, while her right arm, which was hanging over the back of the chair, went to sleep; from this there developed a paresis of the same arm accompanied by contracture and anaesthesia. She tried to pray but could find no words; a length she succeeded in repeating a children's prayer in English. When subsequently a severe and highly complicated hysteria developed, she could only speak, write and understand English, while her native language remained unintelligible to her for eighteen months. - The mother of a very sick child, which had at last fallen asleep, concentrated her whole will-power on keeping still so as not to waken it. Precisely on account of her intention she made a 'clacking' noise with her tongue. (An instance of 'hysterical counter-will'.) This noise was repeated on a subsequent occasion on which she wished to keep perfectly still; and from it there developed a *tic* which, in the form of a clacking with the tongue, occurred over a period of many years whenever she felt excited. - A highly intelligent man was present while his brother had an ankylosed hip-joint extended under an anaesthetic. At the instant at which the joint gave way with a crack, he felt a violent pain in his own hip-joint, which persisted for nearly a year. - Further instances could be quoted.

In other cases the connection is not so simple. It consists only in what might be called a 'symbolic' relation between the precipitating cause and the pathological phenomenon - a relation such as healthy people form in dreams. For instance, a neuralgia may follow upon mental pain or vomiting upon a feeling of moral disgust. We have studied patients who used to make the most copious use of this sort of symbolization. In still other cases it is not possible to understand at first sight how they can be determined in the manner we have suggested. It is precisely the typical hysterical symptoms which fall into this class, such as hemi-anaesthesia, contraction of the field of vision, epileptiform convulsions, and so on. An explanation of our views on this group must be reserved for a fuller discussion of the subject.

Observations such as these seem to us to establish an analogy between the pathogenesis of common hysteria and that of the traumatic neuroses, and to justify an extension of the concept of traumatic hysteria. In traumatic neuroses the operative cause of the illness is not the trifling physical injury but the affect of fright - the psychical trauma. In an analogous manner, our investigations reveal, for many, if not for most, hysterical symptoms, precipitating causes which can only be described as psychical traumas. Any experience which calls up distressing affects - such as those of fright, anxiety, shame or physical pain - may operate as a trauma of this kind; and whether it in fact does so depends naturally enough on the susceptibility of the person affected (as well as on another condition which will be mentioned later). In the case of common hysteria it not infrequently happens that, instead of a single, major trauma, we find a number of partial traumas forming a *group* of provoking causes. These have only been able to exercise a traumatic effect by summation and they belong together in so far as they are in part components of a single story of suffering. There are other cases in which an apparently trivial circumstance combines with the actually operative event or occurs at a time of peculiar susceptibility to stimulation and in this way attains the dignity of a trauma which it would not otherwise have possessed but which thenceforward persists.

But the causal relation between the determining psychical trauma and the hysterical phenomenon is not of a kind implying that the trauma merely acts like an *agent provocateur* in releasing the symptom, which thereafter leads an independent existence. We must presume rather that the psychical trauma - or more precisely the memory of the trauma - acts like a foreign body which long after its entry must continue to be regarded as an agent that is still at work; and we find the evidence for this in a highly remarkable phenomenon which at the same time lends an important *practical* interest to our findings.

For we found, to our great surprise at first, that *each individual hysterical symptom immediately and permanently disappeared when we had succeeded in bringing clearly to light the memory of the event by which it was provoked and in arousing its accompanying affect, and when the patient had described that event in the greatest possible detail and had put the affect into words*. Recollection without affect almost invariably produces no result. The psychical process which originally took place must be repeated as vividly as possible; it must be brought back to its *status nascendi* and then given verbal utterance. Where what we are dealing with are phenomena involving stimuli (spasms, neuralgias and hallucinations) these re-appear once again with the fullest intensity and then vanish for ever. Failures of function, such as paralyses and anaesthesias, vanish in the same way, though, of course, without the temporary intensification being discernible.¹

¹ The possibility of a therapeutic procedure of this kind has been clearly recognized by Delboeuf and Binet, as is shown by the following quotations: 'On s'expliquerait dès lors comment le magnétiseur aide à la guérison. Il remet le sujet dans l'état où le mal s'est manifesté et combat par la parole le même mal, mais renaissant.' ['We can now explain how the hypnotist promotes cure. He puts the subject back into the state in which his trouble first appeared and uses words to combat that trouble, as it now makes a fresh emergence.'] (Delboeuf 1889.) - '... peut-être verra-t-on qu'en reportant le malade par un artifice mental au moment même où le symptôme a apparu pour la première fois, on rend ce malade plus docile à une suggestion curative.' ['... we shall perhaps find that by taking the patient back by mean of a mental artifice to the very moment at which the symptom first appeared, we may make him more susceptible to a therapeutic suggestion.'] (Binet, 1892, 243.) - In Janet's interesting study on mental automatism (1889), there is an account of the cure of a hysterical girl by a method analogous to ours.

It is plausible to suppose that it is a question here of unconscious suggestion: the patient expects to be relieved of his sufferings by this procedure, and it is this expectation, and not the verbal utterance, which is the operative factor. This, however, is not so. The first case of this kind that came under observation dates back to the year 1881, that is to say to the 'pre-suggestion' era. A highly complicated case of hysteria was analysed in this way, and the symptoms, which sprang from separate causes, were separately removed. This observation was made possible by spontaneous auto-hypnoses on the part of the patient, and came as a great surprise to the observer.

We may reverse the dictum '*cessante causa cessat effectus*' ['when the cause ceases the effect ceases'] and conclude from these observations that the determining process continues to operate in some way or other for years - not indirectly, through a chain of intermediate causal links, but as a *directly* releasing cause just as a psychical pain that is remembered in waking consciousness still provokes a lachrymal secretion long after the event. *Hysterics suffer mainly from reminiscences.*¹

¹ In this preliminary communication it is not possible for us to distinguish what is new in it from what has been said by other authors such as Moebius and Strümpell who have held similar views on hysteria to ours. We have found the nearest approach to what we have to say on the theoretical and therapeutic sides of the question in some remarks, published from time to time, by Benedikt. These we shall deal with elsewhere.

II

At first sight it seems extraordinary that events experienced so long ago should continue to operate so intensely - that their recollection should not be liable to the wearing away process to which, after all, we see all our memories succumb. The following considerations may perhaps make this a little more intelligible.

The fading of a memory or the losing of its affect depends on various factors. The most important of these is *whether there has been an energetic reaction to the event that provokes the affect*. By 'reaction' we here understand the whole class of voluntary and involuntary reflexes - from tears to acts of revenge - in which, as experience shows us, the affects are discharged. If this reaction takes place to a sufficient amount a large part of the affect disappears as a result. Linguistic usage bears witness to this fact of daily observation by such phrases as 'to cry oneself out' [*sich ausweinen*], and to 'blow off steam' [*sich austoben*], literally 'to rage oneself out'. If the reaction is suppressed, the affect remains attached to the memory. An injury that has been repaid, even if only in words, is recollected quite differently from one that has had to be accepted. Language recognizes this distinction, too, in its mental and physical consequences; it very characteristically describes an injury that has been suffered in silence as 'a mortification' [*Kränkung*], literally 'making ill'. - The injured person's reaction to the trauma only exercises a completely 'cathartic' effect if it is an *adequate* reaction - as, for instance, revenge. But language serves as a substitute for action; by its help, an affect can be 'abreacted' almost as effectively. In other cases speaking is itself the adequate reflex, when, for instance, it is a lamentation or giving utterance to a tormenting secret, e.g. a confession. If there is no such reaction, whether in deeds or words, or in the mildest cases in tears, any recollection of the event retains its affective tone to begin with.

'Abreaction', however, is not the only method of dealing with the situation that is open to a normal person who has experienced a psychical trauma. A memory of such a trauma, even if it has not been abreacted, enters the great complex of associations, it comes alongside other experiences, which may contradict it, and is subjected to rectification by other ideas. After an accident, for instance, the memory of the danger and the (mitigated) repetition of the fright becomes associated with the memory of what happened afterwards - rescue and the consciousness of present safety. Again, a person's memory of a humiliation is corrected by his putting the facts right, by considering his own worth, etc. In this way a normal person is able to bring about the disappearance of the accompanying affect through the process of association.

To this we must add the general effacement of impressions, the fading of memories which we name 'forgetting' and which wears away those ideas in particular that are no longer affectively operative.

Our observations have shown, on the other hand, that the memories which have become the determinants of hysterical phenomena persist for a long time with astonishing freshness and with the whole of their affective colouring. We must, however, mention another remarkable fact, which we shall later be able to turn to account, namely, that these memories, unlike other memories of their past lives, are not at the patients' disposal. On the contrary, *these experiences are completely absent from the patient's memory when they are in a normal psychical state, or are only present in highly summary form.* Not until they have been questioned under hypnosis do these memories emerge with the undiminished vividness of a recent event.

Thus, for six whole months, one of our patients reproduced under hypnosis with hallucinatory vividness everything that had excited her on the same day of the previous year (during an attack of acute hysteria). A diary kept by her mother with out her knowledge proved the completeness of the reproduction. Another patient, partly under hypnosis and partly during spontaneous attacks, re-lived with hallucinatory clarity all the events of a hysterical psychosis which she had passed through ten years earlier and which she had for the most part forgotten till the moment at which it re-emerged. Moreover, certain memories of aetiological importance which dated back from fifteen to twenty-five years were found to be astonishingly intact and to possess remarkable sensory force, and when they returned they acted with all the affective strength of new experiences.

This can only be explained on the view that these memories constitute an exception in their relation to all the wearing-away processes which we have discussed above. *It appears, that is to say, that these memories correspond to traumas that have not been sufficiently abreacted*; and if we enter more closely into the reasons which have prevented this, we find at least two sets of conditions under which the reaction to the trauma fails to occur.

In the first group are those cases in which the patients have not reacted to a psychical trauma because the nature of the trauma excluded a reaction, as in the case of the apparently irreparable loss of a loved person or because social circumstance made a reaction impossible or because it was a question of things which the patient wished to forget, and therefore intentionally repressed from his conscious thought and inhibited and suppressed. It is precisely distressing things of this kind that, under hypnosis, we find are the basis of hysterical phenomena (e.g. hysterical deliria in saints and nuns, continent women and well-brought-up children).

The second group of conditions are determined, not by the content of the memories but by the psychical states in which the patient received the experiences in question. For we find, under hypnosis, among the causes of hysterical symptoms ideas which are not in themselves significant, but whose persistence is due to the fact that they originated during the prevalence of severely paralysing affects, such as fright, or during positively abnormal psychical states, such as the semi-hypnotic twilight state of day-dreaming, auto-hypnoses, and so on. In such cases it is the nature of the states which makes a reaction to the event impossible.

Both kinds of conditions may, of course, be simultaneously present, and this, in fact, often occurs. It is so when a trauma which is operative in itself takes place while a severely paralysing affect prevails or during a modified state of consciousness. But it also seems to be true that in many people a psychical trauma *produces* one of these abnormal states, which, in turn, makes reaction impossible.

Both of these groups of conditions, however, have in common the fact that the psychical traumas which have not been disposed of by reaction cannot be disposed of either by being worked over by means of association. In the first group the patient is determined to forget the distressing experiences and accordingly excludes them so far as possible from association; while in the second group the associative working-over fails to occur because there is no extensive associative connection between the normal state of consciousness and the pathological ones in which the ideas made their appearance. We shall have occasion immediately to enter further into this matter.

It may therefore be said that the ideas which have become pathological have persisted with such freshness and affective strength because they have been denied the normal wearing-away process by means of abreaction and reproduction in states of uninhibited association.

III

We have stated the conditions which, as our experience shows, are responsible for the development of hysterical phenomena from psychical traumas. In so doing, we have already been obliged to speak of abnormal states of consciousness in which these pathogenic ideas arise, and to emphasize the fact that the recollection of the operative psychical trauma is not to be found in the patient's normal memory but in his memory when he is hypnotized. The longer we have been occupied with these phenomena the more we have become convinced that *the splitting of consciousness which is so striking in the well-known classical cases under the form of 'double conscience' is present to a rudimentary degree in every hysteria, and that a tendency to such dissociation, and with it the emergence of abnormal states of consciousness (which we shall bring together under the term 'hypnoid') is the basic phenomenon of this neurosis.* In these views we concur with Binet and the two Janets, though we have had no experience of the remarkable findings they have made on anaesthetic patients.

We should like to balance the familiar thesis that hypnosis is an artificial hysteria by another - the basis and *sine qua non* of hysteria is the existence of hypnoid states. These states share with one another and with hypnosis, however much they may differ in other respects, one common feature: the ideas which emerge in them are very intense but are cut off from associative communication with the rest of the content of consciousness. Associations may take place between these hypnoid states, and their ideational content can in this way reach a more or less high degree of psychical organization. Moreover, the nature of these states and the extent to which they are cut off from the remaining conscious processes must be supposed to vary just as happens in hypnosis, which ranges from a light drowsiness to somnambulism, from complete recollection to total amnesia.

If hypnoid states of this kind are already present before the onset of the manifest illness, they provide the soil in which the affect plants the pathogenic memory with its consequent somatic phenomena. This corresponds to *dispositional* hysteria. We have found, however, that a severe trauma (such as occurs in a traumatic neurosis) or a laborious suppression (as of a sexual affect, for instance) can bring about a splitting-off of groups of ideas even in people who are in other respects unaffected; and this would be the mechanism of *psychically acquired* hysteria. Between the extremes of these two forms we must assume the existence of a series of cases within which the liability to dissociation in the subject and the affective magnitude of the trauma vary inversely.

We have nothing new to say on the question of the origin of these dispositional hypnoid states. They often, it would seem, grow out of the day-dreams which are so common even in healthy people and to which needlework and similar occupations render women especially prone. Why it is that the 'pathological associations' brought about in these states are so stable and why they have so much more influence on somatic processes than ideas are usually found to do - these questions coincide with the general problem of the effectiveness of hypnotic suggestions. Our observations contribute nothing fresh on this subject. But they throw a light on the contradiction between the dictum 'hysteria is a psychosis' and the fact that among hysterics may be found people of the clearest intellect, strongest will, greatest character and highest critical power. This characterization holds good of their waking thoughts; but in their hypnoid states they are insane, as we all are in dreams. Whereas, however, our dream-psychoses have no effect upon our waking state, the products of hypnoid states intrude into waking life in the form of hysterical symptoms.

IV

What we have asserted of chronic hysterical symptoms can be applied almost completely to hysterical attacks. Charcot, as is well known, has given us a schematic description of the 'major' hysterical attack, according to which four phases can be distinguished in a complete attack: (1) the epileptoid phase, (2) the phase of large movements, (3) the phase of '*attitudes passionelles*' (the hallucinatory phase), and (4) the phase of terminal delirium. Charcot derives all those forms of hysterical attack which are in practice met with more often than the complete '*grande attaque*', from the abbreviation, absence or isolation of these four distinct phases.

Our attempted explanation takes its start from the third of these phases, that of the '*attitudes passionelles*'. Where this is present in a well-marked form, it exhibits the hallucinatory reproduction of a memory which was of importance in bringing about the onset of the hysteria - the memory either of a single major trauma (which we find *par excellence* in what is called traumatic hysteria) or of a series of interconnected part-traumas (such as underlie common hysteria). Or, lastly, the attack may revive the events which have become emphasized owing to their *coinciding* with a moment of special disposition to trauma.

There are also attacks, however, which appear to consist exclusively of motor phenomena and in which the phase of *attitudes passionelles* is absent. If one can succeed in getting into *rapport* with the patient during an attack such as this of generalized clonic spasms or cataleptic rigidity, or during an *attaque de sommeil* [attack of sleep] - or if, better still, one can succeed in provoking the attack under hypnosis - one finds that here, too, there is an underlying memory of the psychical trauma or series of traumas, which usually comes to our notice in a hallucinatory phase.

Thus, a little girl suffered for years from attacks of general convulsions which could well be, and indeed were, regarded as epileptic. She was hypnotized with a view to a differential diagnosis, and promptly had one of her attacks. She was asked what, she was seeing and replied 'The dog! the dog's coming!'; and in fact it turned out that she had had the first of her attacks after being chased by a savage dog. The success of the treatment confirmed the choice of diagnosis.

Again, an employee who had become a hysteric as a result of being ill-treated by his superior, suffered from attacks in which he collapsed and fell into a frenzy of rage, but without uttering a word or giving any sign of a hallucination. It was possible to provoke an attack under hypnosis, and the patient then revealed that he was living through the scene in which his employer had abused him in the street and hit him with a stick. A few days later the patient came back and complained of having had another attack of the same kind. On this occasion it turned out under hypnosis that he had been re-living the scene to which the actual onset of the illness was related: the scene in the law-court when he failed to obtain satisfaction for his maltreatment.

In all other respects, too, the memories which emerge, or can be aroused, in hysterical attacks correspond to the precipitating causes which we have found at the root of *chronic* hysterical symptoms. Like these latter causes, the memories underlying hysterical attacks relate to psychical traumas which have not been disposed of by abreaction or by associative thought activity. Like them, they are, whether completely or in essential elements, out of reach of the memory of normal consciousness and are found to belong to the ideational content of hypnoid states of consciousness with restricted association. Finally, too, the therapeutic test can be applied to them. Our observations have often taught us that a memory of this kind which has hitherto provoked attacks, ceases to be able to do so after the process of reaction and associative correction have been applied to it under hypnosis.

The motor phenomena of hysterical attacks can be interpreted partly as universal forms of reaction appropriate to the affect accompanying the memory (such as kicking about and waving the arms and legs, which even young babies do), partly as a direct expression of these memories; but in part, like the hysterical stigmata found among the chronic symptoms, they cannot be explained in this way.

Hysterical attacks, furthermore, appear in a specially interesting light if we bear in mind a theory that we have mentioned above, namely, that in hysteria groups of ideas originating in hypnoid states are present and that these are cut off from associative connection with the other ideas, but can be associated among themselves, and thus form the more or less highly organized rudiment of a second consciousness, a *condition seconde*. If this is so, a chronic hysterical symptom will correspond to the intrusion of this second state into the somatic innervation which is as a rule under the control of normal consciousness. A hysterical attack, on the other hand, is evidence of a higher organization of this second state. When the attack makes its first appearance, it indicates a moment at which this hypnoid consciousness has obtained control of the subject's whole existence - it points, that is, to an acute hysteria; when it occurs on subsequent occasions and contains a memory it points to a return of that moment. Charcot has already suggested that hysterical attacks are a rudimentary form of a *condition seconde*. During the attack, control over the whole of the somatic innervation passes over to the hypnoid consciousness. Normal consciousness, as well-known observations show, is not always entirely repressed. It may even be aware of the motor phenomena of the attack, while the accompanying psychical events are outside its knowledge.

The typical course of a severe case of hysteria is, as we know, as follows. To begin with, an ideational content is formed during hypnoid states; when this has increased to a sufficient extent, it gains control, during a period of 'acute hysteria', of the somatic innervation and of the patient's whole existence, and creates chronic symptoms and attacks; after this it clears up, apart from certain residues. If the normal personality can regain control, what is left over from the hypnoid ideational content recurs in hysterical attacks and puts the subject back from time to time into similar states, which are themselves once more open to influence and susceptible to traumas. A state of equilibrium, as it were, may then be established between the two psychical groups which are combined in the same person: hysterical attacks and normal life proceed side by side without interfering with each other. An attack will occur spontaneously, just as memories do in normal people; it is, however, possible to provoke one, just as any memory can be aroused in accordance with the laws of association. It can be provoked either by stimulation of a hysterogenic zone or by a new experience which sets it going owing to a similarity with the pathogenic experience. We hope to be able to show that these two kinds of determinant, though they appear to be so unlike, do not differ in essentials, but that in both a hyperaesthetic memory is touched on.

In other cases this equilibrium is very unstable. The attack makes its appearance as a manifestation of the residue of the hypnoid consciousness whenever the normal personality is exhausted and incapacitated. The possibility cannot be dismissed that here the attack may have been divested of its original meaning and may be recurring as a motor reaction without any content.

It must be left to further investigation to discover what it is that determines whether a hysterical personality manifests itself in attacks, in chronic symptoms or in a mixture of the two.

V

It will now be understood how it is that the psychotherapeutic procedure which we have described in these pages has a curative effect. *It brings to an end the operative force of the idea which was not abreacted in the first instance, by allowing its strangulated affect to find a way out through speech; and it subjects it to associative correction by introducing it into normal consciousness (under light hypnosis) or by removing it through the physician's suggestion, as it is done in somnambulism accompanied by amnesia.*

In our opinion the therapeutic advantages of this procedure are considerable. It is of course true that we do not cure hysteria in so far as it is a matter of disposition. We can do nothing against the recurrence of hypnoid states. Moreover, during the productive stage of an acute hysteria our procedure cannot prevent the phenomena which have been so laboriously removed from being at once replaced by fresh ones. But once this acute stage is past, any residues which may be left in the form of chronic symptoms or attacks are often removed, and permanently so, by our method, because it is a radical one; in this respect it seems to us far superior in its efficacy to removal through direct suggestion, as it is practised to-day by psychotherapists.

If by uncovering the psychical mechanism of hysterical phenomena we have taken a step forward along the path first traced so successfully by Charcot with his explanation and artificial imitation of hysterotraumatic paralyses, we cannot conceal from ourselves that this has brought us nearer to an understanding only of the *mechanism* of hysterical symptoms and not of the internal causes of hysteria. We have done no more than touch upon the aetiology of hysteria and in fact have been able to throw light only on its acquired forms - on the bearing of accidental factors on the neurosis.

CASE HISTORIES

(BREUER AND FREUD)

CASE 1

FRÄULEIN ANNA O. (Breuer)

At the time of her falling ill (in 1880) Fräulein Anna O. was twenty-one years old. She may be regarded as having had a moderately severe neuropathic heredity, since some psychoses had occurred among her more distant relatives. Her parents were normal in this respect. She herself had hitherto been consistently healthy and had shown no signs of neurosis during her period of growth. She was markedly intelligent, with an astonishingly quick grasp of things and penetrating intuition. She possessed a powerful intellect which would have been capable of digesting solid mental pabulum and which stood in need of it - though without receiving it after she had left school. She had great poetic and imaginative gifts, which were under the control of a sharp and critical common sense. Owing to this latter quality she was *completely unsuggestible*; she was only influenced by arguments, never by mere assertions. Her willpower was energetic, tenacious and persistent; sometimes it reached the pitch of an obstinacy which only gave way out of kindness and regard for other people.

One of her essential character traits was sympathetic kindness. Even during her illness she herself was greatly assisted by being able to look after a number of poor, sick people, for she was thus able to satisfy a powerful instinct. Her states of feeling always tended to a slight exaggeration, alike of cheerfulness and gloom; hence she was sometimes subject to moods. The element of sexuality was astonishingly undeveloped in her. The patient, whose life became known to me to an extent to which one person's life is seldom known to another, had never been in love; and in all the enormous number of hallucinations which occurred during her illness that element of mental life never emerged.

This girl, who was bubbling over with intellectual vitality, led an extremely monotonous existence in her puritanically-minded family. She embellished her life in a manner which probably influenced her decisively in the direction of her illness, by indulging in systematic day-dreaming, which she described as her 'private theatre'. While everyone thought she was attending, she was living through fairy tales in her imagination; but she was always on the spot when she was spoken to, so that no one was aware of it. She pursued this activity almost continuously while she was engaged on her household duties, which she discharged unexceptionably. I shall presently have to describe the way in which this habitual day-dreaming while she was well passed over into illness without a break.

The course of the illness fell into several clearly separable phases:

(A) Latent incubation. From the middle of July, 1880, till about December 10. This phase of an illness is usually hidden from us; but in this case, owing to its peculiar character, it was completely accessible; and this in itself lends no small pathological interest to the history, I shall describe this phase presently.

(B) The manifest illness. A psychosis of a peculiar kind, paraphasia, a convergent squint, severe disturbances of vision, paralyses (in the form of contractures), complete in the right upper and both lower extremities, partial in the left upper extremity, paresis of the neck muscles. A gradual reduction of the contracture to the right-hand extremities. Some improvement, interrupted by a severe psychical trauma (the death of the patient's father) in April, after which there followed

(C) A period of persisting somnambulism, subsequently alternating with more normal states. A number of chronic symptoms persisted till December, 1881.

(D) Gradual cessation of the pathological states and symptoms up to June, 1882.

In July, 1880, the patient's father, of whom she was passionately fond, fell ill of a peripleuritic abscess which failed to clear up to which he succumbed in April, 1881. During the first months of the illness Anna devoted her whole energy to nursing her father, and no one was much surprised when by degrees her own health greatly deteriorated. No one, perhaps not even the patient herself, knew what was happening to her; but eventually the state of weakness, anaemia and distaste for food became so bad that to her great sorrow she was no longer allowed to continue nursing the patient. The immediate cause of this was a very severe cough, on account of which I examined her for the first time. It was a typical *tussis nervosa*. She soon began to display a marked craving for rest during the afternoon, followed in the evening by a sleep-like state and afterwards a highly excited condition.

At the beginning of December a convergent squint appeared. An ophthalmic surgeon explained this (mistakenly) as being due to paresis of one abducens. On December 11 the patient took to her bed and remained there until April 1.

There developed in rapid succession a series of severe disturbances which were *apparently* quite new: left-sided occipital headache; convergent squint (diplopia), markedly increased by excitement; complaints that the walls of the room seemed to be falling over (affection of the obliquus); disturbances of vision which it was hard to analyse; paresis of the muscles of the front of the neck, so that finally the patient could only move her head by pressing it backwards between her raised shoulders and moving her whole back; contracture and anaesthesia of the right upper, and, after a time, of the right lower extremity. The latter was fully extended, adducted and rotated inwards. Later the same symptom appeared in the left lower extremity and finally in the left arm, of which, however, the fingers to some extent retained the power of movement. So, too, there was no complete rigidity in the shoulder-joints. The contracture reached its maximum in the muscles of the upper arms. In the same way, the region of the elbows turned out to be the most affected by anaesthesia when, at a later stage, it became possible to make a more careful test of this. At the beginning of the illness the anaesthesia could not be efficiently tested, owing to the patient's resistance arising from feelings of anxiety.

It was while the patient was in this condition that I undertook her treatment, and I at once recognized the seriousness of the psychical disturbance with which I had to deal. Two entirely distinct states of consciousness were present which alternated very frequently and without warning and which became more and more differentiated in the course of the illness. In one of these states she recognized her surroundings; she was melancholy and anxious, but relatively normal. In the other state she hallucinated and was 'naughty' - that is to say, she was abusive, used to throw the cushions at people, so far as the contractures at various times allowed, tore buttons off her bed clothes and linen with those of her fingers which she could move, and so on. At this stage of her illness if something had been moved in the room or someone had entered or left it she would complain of having 'lost' some time and would remark upon the gap in her train of conscious thoughts. Since those about her tried to deny this and to soothe her when she complained that she was going mad, she would, after throwing the pillows about, accuse people of doing things to her and leaving her in a muddle, etc.

These '*absences*' had already been observed before she took to her bed; she used then to stop in the middle of a sentence, repeat her last words and after a short pause go on talking. These interruptions gradually increased till they reached the dimensions that have just been described; and during the climax of the illness, when the contractures had extended to the left side of her body, it was only for a short time during the day that she was to any degree normal. But the disturbances invaded even her moments of relatively clear consciousness. There were extremely rapid changes of mood leading to excessive but quite temporary high spirits, and at other times severe anxiety, stubborn opposition to every therapeutic effort and frightening hallucinations of black snakes, which was how she saw her hair, ribbons and similar things. At the same time she kept on telling herself not to be so silly: what she was seeing was really only her hair, etc. At moments when her mind was quite clear she would complain of the profound darkness in her head, of not being able to think, of becoming blind and deaf, of having two selves, a real one and an evil one which forced her to behave badly, and so on.

In the afternoons she would fall into a somnolent state which lasted till about an hour after sunset. She would then wake up and complain that something was tormenting her - or rather, she would keep repeating in the impersonal form 'tormenting, tormenting'. For alongside of the development of the contractures there appeared a deep-going functional disorganization of her speech. It first became noticeable that she was at a loss to find words, and this difficulty gradually increased. Later she lost her command of grammar and syntax; she no longer conjugated verbs, and eventually she used only infinitives, for the most part incorrectly formed from weak past participles; and she omitted both the definite and indefinite article. In the process of time she became almost completely deprived of words. She put them together laboriously out of four or five languages and became almost unintelligible. When she tried to write (until her contractures entirely prevented her doing so) she employed the same jargon. For two weeks she became completely dumb and in spite of making great and continuous efforts to speak she was unable to say a syllable. And now for the first time the psychical mechanism of the disorder became clear. As I knew, she had felt very much offended over something and had determined not to speak about it. When I guessed this and obliged her to talk about it, the inhibition, which had made any other kind of utterance impossible as well, disappeared.

This change coincided with a return of the power of movement to the extremities of the left side of her body, in March, 1881. Her paraphasia receded; but thenceforward she spoke only in English - apparently, however, without knowing that she was doing so. She had disputes with her nurse who was, of course, unable to understand her. It was only some months later that I was able to convince her that she was talking English. Nevertheless, she herself could still understand the people about her who talked German. Only in moments of extreme anxiety did her power of speech desert her entirely, or else she would use a mixture of all sorts of languages. At times when she was at her very best and most free, she talked French and Italian. There was complete amnesia between these times and those at which she talked English. At this point, too, her squint began to diminish and made its appearance only at moments of great excitement. She was once again able to support her head. On the first of April she got up for the first time.

On the fifth of April her adored father died. During her illness she had seen him very rarely and for short periods. This was the most severe psychical trauma that she could possibly have experienced. A violent outburst of excitement was succeeded by profound stupor which lasted about two days and from which she emerged in a greatly changed state. At first she was far quieter and her feelings of anxiety were much diminished. The contracture of her right arm and leg persisted as well as their anaesthesia, though this was not deep. There was a high degree of restriction of the field of vision: in a bunch of flowers which gave her much pleasure she could only see one flower at a time. She complained of not being able to recognize people. Normally, she said, she had been able to recognize faces without having to make any deliberate effort; now she was obliged to do laborious 'recognizing work'¹ and had to say to herself 'this person's nose is such-and-such, his hair is such-and-such, so he must be so-and-so'. All the people she saw seemed like wax figures without any connection with her. She found the presence of some of her close relatives very distressing and this negative attitude grew continually stronger. If someone whom she was ordinarily pleased to see came into the room, she would recognize him and would be aware of things for a short time, but would soon sink back into her own broodings and her visitor was blotted out. I was the only person whom she always recognized when I came in; so long as I was talking to her she was always in contact with things and lively, except for the sudden interruptions caused by one of her hallucinatory '*absences*'.

She now spoke only English and could not understand what was said to her in German. Those about her were obliged to talk to her in English; even the nurse learned to make herself to some extent understood in this way. She was, however, able to read French and Italian. If she had to read one of these aloud, what she produced, with extraordinary fluency, was an admirable extempore English translation.

She began writing again, but in a peculiar fashion. She wrote with her left hand, the less stiff one, and she used Roman printed letters, copying the alphabet from her edition of Shakespeare.

She had eaten extremely little previously, but now she refused nourishment altogether. However, she allowed me to feed her, so that she very soon began to take more food. But she never consented to eat bread. After her meal she invariably rinsed out her mouth and even did so if, for any reason, she had not eaten anything - which shows how absent-minded she was about such things.

¹ [In English in the original.]

Her somnolent states in the afternoon and her deep sleep after sunset persisted. If, after this, she had talked herself out (I shall have to explain what is meant by this later) she was clear in mind, calm and cheerful.

This comparatively tolerable state did not last long. Some ten days after her father's death a consultant was brought in, whom, like all strangers, she completely ignored while I demonstrated all her peculiarities to him. 'That's like an examination,'¹ she said, laughing, when I got her to read a French text aloud in English. The other physician intervened in the conversation and tried to attract her attention, but in vain. It was a genuine 'negative hallucination' of the kind which has since so often been produced experimentally. In the end he succeeded in breaking through it by blowing smoke in her face. She suddenly saw a stranger before her, rushed to the door to take away the key and fell unconscious to the ground. There followed a short fit of anger and then a severe attack of anxiety which I had great difficulty in calming down. Unluckily I had to leave Vienna that evening, and when I came back several days later I found the patient much worse. She had gone entirely without food the whole time, was full of anxiety and her hallucinatory *absences* were filled with terrifying figures, death's heads and skeletons. Since she acted these things through as though she was experiencing them and in part put them into words, the people around her became aware to a great extent of the content of these hallucinations.

The regular order of things was: the somnolent state in the afternoon, followed after sunset by the deep hypnosis for which she invented the technical name of 'clouds'.² If during this she was able to narrate the hallucinations she had had in the course of the day, she would wake up clear in mind, calm and cheerful. She would sit down to work and write or draw far into the night quite rationally. At about four she would go to bed. Next day the whole series of events would be repeated. It was a truly remarkable contrast: in the day-time the irresponsible patient pursued by hallucinations, and at night the girl with her mind completely clear.

¹ [In English in the original.]

² [In English in the original.]

In spite of her euphoria at night, her psychical condition deteriorated steadily. Strong suicidal impulses appeared which made it seem inadvisable for her to continue living on the third floor. Against her will, therefore, she was transferred to a country house in the neighbourhood of Vienna (on June 7, 1881). I had never threatened her with this removal from her home, which she regarded with horror, but she herself had, without saying so, expected and dreaded it. This event made it clear once more how much the affect of anxiety dominated her psychical disorder. Just as after her father's death a calmer condition had set in, so now, when what she feared had actually taken place, she once more became calmer. Nevertheless, the move was immediately followed by three days and nights completely without sleep or nourishment, by numerous attempts at suicide (though, so long as she was in a garden, these were not dangerous), by smashing windows and so on, and by hallucinations unaccompanied by *absences* which she was able to distinguish easily from her other hallucinations. After this she grew quieter, let the nurse feed her and even took chloral at night.

Before continuing my account of the case, I must go back once more and describe one of its peculiarities which I have hitherto mentioned only in passing. I have already said that throughout the illness up to this point the patient fell into a somnolent state every afternoon and that after sunset this period passed into a deeper sleep - 'clouds'. (It seems plausible to attribute this regular sequence of events merely to her experience while she was nursing her father, which she had had to do for several months. During the nights she had watched by the patient's bedside or had been awake anxiously listening till the morning; in the afternoons she had lain down for a short rest, as is the usual habit of nurses. This pattern of waking at night and sleeping in the afternoons seems to have been carried over into her own illness and to have persisted long after the sleep had been replaced by a hypnotic state.) After the deep sleep had lasted about an hour she grew restless, tossed to and fro and kept repeating 'tormenting, tormenting', with her eyes shut all the time. It was also noticed how, during her *absences* in day-time she was obviously creating some situation or episode to which she gave a clue with a few muttered words. It happened then - to begin with accidentally but later intentionally - that someone near her repeated one of these phrases of hers while she was complaining about the 'tormenting'. She at once joined in and began to paint some situation or tell some story, hesitatingly at first and in her paraphasic jargon; but the longer she went on the more fluent she became, till at last she was speaking quite correct German. (This applies to the early period before she began talking English only.) The stories were always sad and some of them very charming, in the style of Hans Andersen's *Picture-book without Pictures*, and, indeed, they were probably constructed on that model. As a rule their starting-point or central situation was of a girl anxiously sitting by a sick-bed. But she also built up her stories on quite other topics. - A few moments after she had finished her narrative she would wake up, obviously calmed down, or, as she called it, '*gehäglich*'.¹ During the night she would again become restless, and in the morning, after a couple of hours' sleep, she was visibly involved in some other set of ideas. - If for any reason she was unable to tell me the story during her evening hypnosis she failed to calm down afterwards, and on the following day she had to tell me *two* stories in order for this to happen.

¹ [She used this made-up word instead of the regular German '*behaglich*', meaning 'comfortable'.]

The essential features of this phenomenon - the mounting up and intensification of her *absences* into her auto-hypnosis in the evening, the effect of the products of her imagination as psychical stimuli and the easing and removal of her state of stimulation when she gave utterance to them in her hypnosis - remained constant throughout the whole eighteen months during which she was under observation.

The stories naturally became still more tragic after her father's death. It was not, however, until the deterioration of her mental condition, which followed when her state of somnambulism was forcibly broken into in the way already described, that her evening narratives ceased to have the character of more or less freely-created poetical compositions and changed into a string of frightful and terrifying hallucinations. (It was already possible to arrive at these from the patient's behaviour during the day.) I have already described how completely her mind was relieved when, shaking with fear and horror, she had reproduced these frightful images and given verbal utterance to them.

While she was in the country, when I was unable to pay her daily visits, the situation developed as follows. I used to visit her in the evening, when I knew I should find her in her hypnosis, and I then relieved her of the whole stock of imaginative products which she had accumulated since my last visit. It was essential that this should be effected completely if good results were to follow. When this was done she became perfectly calm, and next day she would be agreeable, easy to manage, industrious and even cheerful; but on the second day she would be increasingly moody, contrary and unpleasant, and this would become still more marked on the third day. When she was like this it was not always easy to get her to talk, even in her hypnosis. She aptly described this procedure, speaking seriously, as a 'talking cure'¹, while she referred to it jokingly as 'chimney-sweeping'.¹ She knew that after she had given utterance to her hallucinations she would lose all her obstinacy and what she described as her 'energy'; and when, after some comparatively long interval, she was in a bad temper, she would refuse to talk, and I was obliged to overcome her unwillingness by urging and pleading and using devices such as repeating a formula with which she was in the habit of introducing her stories. But she would never begin to talk until she had satisfied herself of my identity by carefully feeling my hands. On those nights on which she had not been calmed by verbal utterance it was necessary to fall back upon chloral. I had tried it on a few earlier occasions, but I was obliged to give her 5 grammes, and sleep was preceded by a state of intoxication which lasted for some hours. When I was present this state was euphoric, but in my absence it was highly disagreeable and characterized by anxiety as well as excitement. (It may be remarked incidentally that this severe state of intoxication made no difference to her contractures.) I had been able to avoid the use of narcotics, since the verbal utterance of her hallucinations calmed her even though it might not induce sleep; but when she was in the country the nights on which she had not obtained hypnotic relief were so unbearable that in spite of everything it was necessary to have recourse to chloral. But it became possible gradually to reduce the dose.

¹ [In English in the original.]

The persisting somnambulism did not return. But on the other hand the alternation between two states of consciousness persisted. She used to hallucinate in the middle of a conversation, run off, start climbing up a tree, etc. If one caught hold of her, she would very quickly take up her interrupted sentence without knowing anything about what had happened in the interval. All these hallucinations, however, came up and were reported on in her hypnosis.

Her condition improved on the whole. She took nourishment without difficulty and allowed the nurse to feed her; except that she asked for bread but rejected it the moment it touched her lips. The paralytic contracture of the leg diminished greatly. There was also an improvement in her power of judgement and she became much attached to my friend Dr. B., the physician who visited her. She derived much benefit from a Newfoundland dog which was given to her and of which she was passionately fond. On one occasion, though, her pet made an attack on a cat, and it was splendid to see the way in which the frail girl seized a whip in her left hand and beat off the huge beast with it to rescue his victim. Later, she looked after some poor, sick people, and this helped her greatly.

It was after I returned from a holiday trip which lasted several weeks that I received the most convincing evidence of the pathogenic and exciting effect brought about by the ideational complexes which were produced during her *absences*, or *condition seconde*, and of the fact that these complexes were disposed of by being given verbal expression during hypnosis. During this interval no 'talking cure' had been carried out, for it was impossible to persuade her to confide what she had to say to anyone but me - not even to Dr. B. to whom she had in other respects become devoted. I found her in a wretched moral state, inert, unamenable, ill-tempered, even malicious. It became plain from her evening stories that her imaginative and poetic vein was drying up. What she reported was more and more concerned with her hallucinations and, for instance, the things that had annoyed her during the past days. These were clothed in imaginative shape, but were merely formulated in stereotyped images rather than elaborated into poetic productions. But the situation only became tolerable after I had arranged for the patient to be brought back to Vienna for a week and evening after evening made her tell me three to five stories. When I had accomplished this, everything that had accumulated during the weeks of my absence had been worked off. It was only now that the former rhythm was re-established: on the day after her giving verbal utterance to her phantasies she was amiable and cheerful, on the second day she was more irritable and less agreeable and on the third positively 'nasty'. Her moral state was a function of the time that had elapsed since her last utterance. This was because every one of the spontaneous products of her imagination and every event which had been assimilated by the pathological part of her mind persisted as a psychical stimulus until it had been narrated in her hypnosis, after which it completely ceased to operate.

When, in the autumn, the patient returned to Vienna (though to a different house from the one in which she had fallen ill), her condition was bearable, both physically and mentally; for very few of her experiences - in fact only her more striking ones - were made into psychical stimuli in a pathological manner. I was hoping for a continuous and increasing improvement, provided that the permanent burdening of her mind with fresh stimuli could be prevented by her giving regular verbal expression to them. But to begin with I was disappointed. In December there was a marked deterioration of her psychical condition. She once more became excited, gloomy and irritable. She had no more 'really good days' even when it was impossible to detect anything that was remaining 'stuck' inside her. Towards the end of December, at Christmas time, she was particularly restless, and for a whole week in the evenings she told me nothing new but only the imaginative products which she had elaborated under the stress of great anxiety and emotion during the Christmas of 1880. When the scenes had been completed she was greatly relieved.

A year had now passed since she had been separated from her father and had taken to her bed, and from this time on her condition became clearer and was systematized in a very peculiar manner. Her alternating states of consciousness, which were characterized by the fact that, from morning onwards, her *absences* (that is to say, the emergence of her *condition seconde*) always became more frequent as the day advanced and took entire possession by the evening - these alternating states had differed from each other previously in that one (the first) was normal and the second alienated; now, however, they differed further in that in the first she lived, like the rest of us, in the winter of 1881-2, whereas in the second she lived in the winter of 1880-1, and had completely forgotten all the subsequent events. The one thing that nevertheless seemed to remain conscious most of the time was the fact that her father had died. She was carried back to the previous year with such intensity that in the new house she hallucinated her old room, so that when she wanted to go to the door she knocked up against the stove which stood in the same relation to the window as the door did in the old room. The change-over from one state to another occurred spontaneously but could also be very easily brought about by any sense-impression which vividly recalled the previous year. One had only to hold up an orange before her eyes (oranges were what she had chiefly lived on during the first part of her illness) in order to carry her over from the year 1882 to the year 1881. But this transfer into the past did not take place in a general or indefinite manner; she lived through the previous winter day by day. I should only have been able to *suspect* that this was happening, had it not been that every evening during the hypnosis she talked through whatever it was that had excited her on the same day in 1881, and had it not been that a private diary kept by her mother in 1881 confirmed beyond a doubt the occurrence of the underlying events. This re-living of the previous year continued till the illness came to its final close in June, 1882.

It was interesting here, too, to observe the way in which these revived psychical stimuli belonging to her secondary state made their way over into her first, more normal one. It happened, for instance, that one morning the patient said to me laughingly that she had no idea what was the matter but she was angry with me. Thanks to the diary I knew what was happening; and, sure enough, this was gone through again in the evening hypnosis: I had annoyed the patient very much on the same evening in 1881. Or another time she told me there was something the matter with her eyes; she was seeing colours wrong. She knew she was wearing a brown dress but she saw it as a blue one. We soon found that she could distinguish all the colours of the visual test-sheets correctly and clearly, and that the disturbance only related to the dress-material. The reason was that during the same period in 1881 she had been very busy with a dressing-gown for her father, which was made with the same material as her present dress, but was blue instead of brown. Incidentally, it was often to be seen that these emergent memories showed their effect in advance; the disturbance of her normal state would occur earlier on, and the memory would only gradually be awakened in her *condition seconde*.

Her evening hypnosis was thus heavily burdened, for we had to talk off not only her contemporary imaginative products but also the events and 'vexations'¹ of 1881. (Fortunately I had already relieved her at the time of the imaginative products of that year.) But in addition to all this the work that had to be done by the patient and her physician was immensely increased by a third group of separate disturbances which had to be disposed of in the same manner. These were the psychical events involved in the period of incubation of the illness between July and December, 1880; it was they that had produced the whole of the hysterical phenomena, and when they were brought to verbal utterance the symptoms disappeared.

When this happened for the first time - when, as a result of an accidental and spontaneous utterance of this kind, during the evening hypnosis, a disturbance which had persisted for a considerable time vanished - I was greatly surprised. It was in the summer during a period of extreme heat, and the patient was suffering very badly from thirst; for, without being able to account for it in any way, she suddenly found it impossible to drink. She would take up the glass of water she longed for, but as soon as it touched her lips she would push it away like some one suffering from hydrophobia. As she did this, she was obviously in an *absence* for a couple of seconds. She lived only on fruit, such as melons, etc., so as to lessen her tormenting thirst. This had lasted for some six weeks, when one day during hypnosis she grumbled about her English lady-companion whom she did not care for, and went on to describe, with every sign of disgust, how she had once gone into that lady's room and how her little dog - horrid creature! - had drunk out of a glass there. The patient had said nothing, as she had wanted to be polite. After giving further energetic expression to the anger she had held back, she asked for something to drink, drank a large quantity of water without any difficulty and woke from her hypnosis with the glass at her lips; and thereupon the disturbance vanished, never to return. A number of extremely obstinate whims were similarly removed after she had described the experiences which had given rise to them. She took a great step forward when the first of her chronic symptoms disappeared in the same way - the contracture of her right leg, which, it is true, had already diminished a great deal. These findings - that in the case of this patient the hysterical phenomena disappeared as soon as the event which had given rise to them was reproduced in her hypnosis - made it possible to arrive at a therapeutic technical procedure which left nothing to be desired in its logical consistency and systematic application. Each individual symptom in this complicated case was taken separately in hand; all the occasions on which it had appeared were described in reverse order, starting before the time when the patient became bed-ridden and going back to the event which had led to its first appearance. When this had been described the symptom was permanently removed.

¹ [In English in the original.]

In this way her paralytic contractures and anaesthesias, disorders of vision and hearing of every sort, neuralgias, coughing, tremors, etc., and finally her disturbances of speech were 'talked away'. Amongst the disorders of vision, the following, for instance, were disposed of separately: the convergent squint with diplopia; deviation of both eyes to the right, so that when her hand reached out for something it always went to the left of the object; restriction of the visual field; central amblyopia; macropsia; seeing a death's head instead of her father; inability to read. Only a few scattered phenomena (such, for instance, as the extension of the paralytic contractures to the left side of her body) which had developed while she was confined to bed, were untouched by this process of analysis, and it is probable, indeed, that they in fact had no immediate physical cause.

It turned out to be quite impracticable to shorten the work by trying to elicit in her memory straight away the first provoking cause of her symptoms. She was unable to find it, grew confused, and things proceeded even more slowly than if she was allowed quietly and steadily to follow back the thread of memories on which she had embarked. Since the latter method, however, took too long in the evening hypnosis, owing to her being over-strained and distraught by 'talking out' the two other sets of experiences - and owing, too, to the reminiscences needing time before they could attain sufficient vividness - we evolved the following procedure. I used to visit her in the morning and hypnotize her. (Very simple methods of doing this were arrived at empirically.) I would next ask her to concentrate her thoughts on the symptom we were treating at the moment and to tell me the occasions on which it had appeared. The patient would proceed to describe in rapid succession and under brief headings the external events concerned and these I would jot down. During her subsequent evening hypnosis she would then, with the help of my notes, give me a fairly detailed account of these circumstances.

An example will show the exhaustive manner in which she accomplished this. It was our regular experience that the patient did not hear when she was spoken to. It was possible to differentiate this passing habit of not hearing as follows:

(a) Not hearing when someone came in, while her thoughts were abstracted. 108 separate detailed instances of this, mentioning the persons and circumstances, often with dates. First instance: not hearing her father come in.

(b) Not understanding when several people were talking. 27 instances. First instance: her father, once more, and an acquaintance.

(c) Not hearing when she was alone and directly addressed. 50 instances. Origin: her father having vainly asked her for some wine.

(d) Deafness brought on by being shaken (in a carriage, etc.). 15 instances. Origin: having been shaken angrily by her young brother when he caught her one night listening at the sick room door.

(e) Deafness brought on by fright at a noise. 37 instances. Origin: a choking fit of her father's, caused by swallowing the wrong way.

(f) Deafness during deep *absence*. 12 instances.

(g) Deafness brought on by listening hard for a long time, so that when she was spoken to she failed to hear. 54 instances.

Of course all these episodes were to a great extent identical in so far as they could be traced back to states of abstraction or *absences* or to fright. But in the patient's memory they were so clearly differentiated, that if she happened to make a mistake in their sequence she would be obliged to correct herself and put them in the right order; if this was not done her report came to a standstill. The events she described were so lacking in interest and significance and were told in such detail that there could be no suspicion of their having been invented. Many of these incidents consisted of purely internal experiences and so could not be verified; others of them (or circumstances attending them) were within the recollection of people in her environment.

This example, too, exhibited a feature that was always observable when a symptom was being 'talked away': the particular symptom emerged with greater force while she was discussing it. Thus during the analysis of her not being able to hear she was so deaf that for part of the time I was obliged to communicate with her in writing. The first provoking cause was habitually a fright of some kind, experienced while she was nursing her father - some oversight on her part, for instance.

The work of remembering was not always an easy matter and sometimes the patient had to make great efforts. On one occasion our whole progress was obstructed for some time because a recollection refused to emerge. It was a question of a particularly terrifying hallucination. While she was nursing her father she had seen him with a death's head. She and the people with her remembered that once, while she still appeared to be in good health, she had paid a visit to one of her relatives. She had opened the door and all at once fallen down unconscious. In order to get over the obstruction to our progress she visited the same place again and, on entering the room, again fell to the ground unconscious. During her subsequent evening hypnosis the obstacle was surmounted. As she came into the room, she had seen her pale face reflected in a mirror hanging opposite the door; but it was not herself that she saw but her father with a death's head. - We often noticed that her dread if a memory, as in the present instance, inhibited its emergence, and this had to be brought about forcibly by the patient or physician.

The following incident, among others, illustrates the high degree of logical consistency of her states. During this period, as has already been explained, the patient was always in her *condition seconde* - that is, in the year 1881 - at night. On one occasion she woke up during the night, declaring that she had been taken away from home once again, and became so seriously excited that the whole household was alarmed. The reason was simple. During the previous evening the talking cure had cleared up her disorder of vision, and this applied also to her *condition seconde*. Thus when she woke up in the night she found herself in a strange room, for her family had moved house in the spring of 1881. Disagreeable events of this kind were avoided by my always (at her request) shutting her eyes in the evening and giving her a suggestion that she would not be able to open them till I did so myself on the following morning. The disturbance was only repeated once, when the patient cried in a dream and opened her eyes on waking up from it.

Since this laborious analysis for her symptoms dealt with the summer months of 1880, which was the preparatory period of her illness, I obtained complete insight into the incubation and pathogenesis of this case of hysteria, and I will now describe them briefly.

In July, 1880, while he was in the country, her father fell seriously ill of a sub-pleural abscess. Anna shared the duties of nursing him with her mother. She once woke up during the night in great anxiety about the patient, who was in a high fever; and she was under the strain of expecting the arrival of a surgeon from Vienna who was to operate. Her mother had gone away for a short time and Anna was sitting at the bedside with her right arm over the back of her chair. She fell into a waking dream and saw a black snake coming towards the sick man from the wall to bite him. (It is most likely that there were in fact snakes in the field behind the house and that these had previously given the girl a fright; they would thus have provided the material for her hallucination.) She tried to keep the snake off, but it was as though she was paralysed. Her right arm, over the back of the chair, had gone to sleep and had become anaesthetic and paretic; and when she looked at it the fingers turned into little snakes with death's heads (the nails). (It seems probable that she had tried to use her paralysed right arm to drive off the snake and that its anaesthesia and paralysis had consequently become associated with the hallucination of the snake.) When the snake vanished, in her terror she tried to pray. But language failed her: she could find no tongue in which to speak, till at last she thought of some children's verses in English and then found herself able to think and pray in that language. The whistle of the train that was bringing the doctor whom she expected broke the spell.

Next day, in the course of a game, she threw a quoit into some bushes; and when she went to pick it out, a bent branch revived her hallucination of the snake, and simultaneously her right arm became rigidly extended. Thenceforward the same thing invariably occurred whenever the hallucination was recalled by some object with a more or less snake-like appearance. This hallucination, however, as well as the contracture only appeared during the short *absences* which became more and more frequent from that night onwards. (The contracture did not become stabilized until December, when the patient broke down completely and took to her bed permanently.) As a result of some particular event which I cannot find recorded in my notes and which I no longer recall, the contracture of the right leg was added to that of the right arm.

Her tendency to auto-hypnotic *absences* was from now on established. On the morning after the night I have described, while she was waiting for the surgeon's arrival, she fell into such a fit of abstraction that he finally arrived in the room without her having heard his approach. Her persistent anxiety interfered with her eating and gradually led to intense feelings of nausea. Apart from this, indeed, each of her hysterical symptoms arose during an affect. It is not quite certain whether in every case a momentary state of *absence* was involved, but this seems probable in view of the fact that in her waking state the patient was totally unaware of what had been going on.

Some of her symptoms, however, seem not to have emerged in her *absences* but merely in an affect during her waking life; but if so, they recurred in just the same way. Thus we were able to trace back all of her different disturbances of vision to different, more or less clearly determining causes. For instance, on one occasion, when she was sitting by her father's bedside with tears in her eyes, he suddenly asked her what time it was. She could not see clearly; she made a great effort, and brought her watch near to her eyes. The face of the watch now seemed very big - thus accounting for her macropsia and convergent squint. Or again, she tried hard to suppress her tears so that the sick man should not see them.

A dispute, in the course of which she suppressed a rejoinder, caused a spasm of the glottis, and this was repeated on every similar occasion.

She lost the power of speech (*a*) as a result of fear, after her first hallucination at night, (*b*) after having suppressed a remark another time (by active inhibition), (*c*) after having been unjustly blamed for something and (*d*) on every analogous occasion (when she felt mortified). She began coughing for the first time when once, as she was sitting at her father's bedside, she heard the sound of dance music coming from a neighbouring house, felt a sudden wish to be there, and was overcome with self-reproaches. Thereafter, throughout the whole length of her illness she reacted to any markedly rhythmical music with a *tussis nervosa*.

I cannot feel much regret that the incompleteness of my notes makes it impossible for me to enumerate all the occasions on which her various hysterical symptoms appeared. She herself told me them in every single case, with the one exception I have mentioned; and, as I have already said, each symptom disappeared after she had described its first occurrence.

In this way, too, the whole illness was brought to a close. The patient herself had formed a strong determination that the whole treatment should be finished by the anniversary of the day on which she was moved into the country. At the beginning of June, accordingly, she entered into the 'talking cure' with the greatest energy. On the last day - by the help of re-arranging the room so as to resemble her father's sickroom - she reproduced the terrifying hallucination which I have described above and which constituted the root of her whole illness. During the original scene she had only been able to think and pray in English; but immediately after its reproduction she was able to speak German. She was moreover free from the innumerable disturbances which she had previously exhibited. After this she left Vienna and travelled for a while; but it was a considerable time before she regained her mental balance entirely. Since then she has enjoyed complete health.

Although I have suppressed a large number of quite interesting details, this case history of Anna O. has grown bulkier than would seem to be required for a hysterical illness that was not in itself of an unusual character. It was, however, impossible to describe the case without entering into details, and its features seem to me of sufficient importance to excuse this extensive report. In just the same way, the eggs of the echinoderm are important in embryology, not because the sea urchin is a particularly interesting animal but because the protoplasm of its eggs is transparent and because what we observe in them thus throws light on the probable course of events in eggs whose protoplasm is opaque. The interest of the present case seems to me above all to reside in the extreme clarity and intelligibility of its pathogenesis.

There were two psychical characteristics present in the girl while she was still completely healthy which acted as predisposing causes for her subsequent hysterical illness:

(1) Her monotonous family life and the absence of adequate intellectual occupation left her with an unemployed surplus of mental liveliness and energy, and this found an outlet in the constant activity of her imagination.

(2) This led to a habit of day-dreaming (her 'private theatre'), which laid the foundations for a dissociation of her mental personality. Nevertheless a dissociation of this degree is still within the bounds of normality. Reveries and reflections during a more or less mechanical occupation do not in themselves imply a pathological splitting of consciousness, since if they are interrupted - if, for instance, the subject is spoken to - the normal unity of consciousness is restored; nor, presumably, is any amnesia present. In the case of Anna O., however, this habit prepared the ground upon which the affect of anxiety and dread was able to establish itself in the way I have described, when once that affect had transformed the patient's habitual day-dreaming into a hallucinatory *absence*. It is remarkable how completely the earliest manifestation of her illness in its beginnings already exhibited its main characteristics, which afterwards remained unchanged for almost two years. These comprised the existence of a second state of consciousness which first emerged as a temporary *absence* and later became organized into a '*double conscience*'; an inhibition of speech, determined by the affect of anxiety, which found a chance discharge in the English verses; later on, paraphasia and loss of her mother-tongue, which was replaced by excellent English; and lastly the accidental paralysis of her right arm, due to pressure, which later developed into a contractural paresis and anaesthesia on her right side. The mechanism by which this latter affection came into being agreed entirely with Charcot's theory of traumatic hysteria - a slight trauma occurring during a state of hypnosis.

But whereas the paralysis experimentally provoked by Charcot in his patients became stabilized immediately, and whereas the paralysis caused in sufferers from traumatic neuroses by a severe traumatic shock sets in at once, the nervous system of this girl put up a successful resistance for four months. Her contracture, as well as the other disturbances which accompanied it set in only during the short *absences* in her *condition seconde*, and left her during her normal state in full control of her body and possession of her senses; so that nothing was noticed either by herself or by those around her, though it is true that the attention of the latter was centred upon the patient's sick father and was consequently diverted from her.

Since, however, her absences with their total amnesia and accompanying hysterical phenomena grew more and more frequent from the time of her first hallucinatory auto-hypnosis, the opportunities multiplied for the formation of new symptoms of the same kind, and those that had already been formed became more strongly entrenched by frequent repetition. In addition to this, it gradually came about that any sudden distressing affect would have the same result as an *absence* (though, indeed, it is possible that such affects actually *caused* a temporary *absence* in every case); chance coincidences set up pathological associations and sensory or motor disturbances, which thenceforward appeared along with the affect. But hitherto this only occurred for fleeting moments. Before the patient took permanently to her bed she had already developed the whole assemblage of hysterical phenomena, without anyone knowing it. It was only after the patient had broken down completely owing to exhaustion brought about by lack of nourishment, insomnia and constant anxiety, and only after she had begun to pass more time in her *condition seconde* than in her normal state, that the hysterical phenomena extended to the latter as well and changed from intermittent acute symptoms into chronic ones.

The question now arises how far the patient's statements are to be trusted and whether the occasions and mode of origin of the phenomena were really as she represented them. So far as the more important and fundamental events are concerned, the trustworthiness of her account seems to me to be beyond question. As regards the symptoms disappearing after being 'talked away', I cannot use this as evidence; it may very well be explained by suggestion. But I always found the patient entirely truthful and trustworthy. The things she told me were intimately bound up with what was most sacred to her. Whatever could be checked by other people was fully confirmed. Even the most highly gifted girl would be incapable of concocting a tissue of data with such a degree of internal consistency as was exhibited in the history of this case. It cannot be disputed, however, that precisely her consistency may have led her (in perfectly good faith) to assign to some of her symptoms a precipitating cause which they did not in fact possess. But this suspicion, too, I consider unjustified. The very insignificance of so many of those causes, the irrational character of so many of the connections involved, argue in favour of their reality. The patient could not understand how it was that dance music made her cough; such a construction is too meaningless to have been deliberate. (It seemed very likely to me, incidentally, that each of her twinges of conscience brought on one of her regular spasms of the glottis and that the motor impulses which she felt - for she was very fond of dancing - transformed the spasm into a *tussis nervosa*.) Accordingly, in my view the patient's statements were entirely trustworthy and corresponded to the facts.

And now we must consider how far it is justifiable to suppose that hysteria is produced in an analogous way in other patients, and that the process is similar where no such clearly distinct *condition seconde* has become organized. I may advance in support of this view the fact that in the present case, too, the story of the development of the illness would have remained completely unknown alike to the patient and the physician if it had not been for her peculiarity of remembering things in hypnosis, as I have described, and of relating what she remembered. While she was in her waking state she knew nothing of all this. Thus it is impossible to arrive at what is happening in other cases from an examination of the patients while in a waking state, for with the best will in the world they can give one no information. And I have already pointed out how little those surrounding the present patient were able to observe of what was going on. Accordingly, it would only be possible to discover the state of affairs in other patients by means of some such procedure as was provided in the case of Anna O. by her auto-hypnoses. Provisionally we can only express the view that trains of events similar to those here described occur more commonly than our ignorance of the pathogenic mechanism concerned has led us to suppose.

When the patient had become confined to her bed, and her consciousness was constantly oscillating between her normal and her 'secondary' state, the whole host of hysterical symptoms, which had arisen separately and had hitherto been latent, became manifest, as we have already seen, as chronic symptoms. There was now added to these a new group of phenomena which seemed to have had a different origin: the paralytic contractures of her left extremities and the paresis of the muscles raising her head. I distinguish them from the other phenomena because when once they had disappeared they never returned, even in the briefest or mildest form or during the concluding and recuperative phase, when all the other symptoms became active again after having been in abeyance for some time. In the same way, they never came up in the hypnotic analyses and were not traced back to emotional or imaginative sources. I am therefore inclined to think that their appearance was not due to the same psychical process as was that of the other symptoms, but is to be attributed to a secondary extension of that unknown condition which constitutes the somatic foundation of hysterical phenomena.

Throughout the entire illness her two states of consciousness persisted side by side: the primary one in which she was quite normal psychically, and the secondary one which may well be likened to a dream in view of its wealth of imaginative products and hallucinations, its large gaps of memory and the lack of inhibition and control in its associations. In this secondary state the patient was in a condition of alienation. The fact that the patient's mental condition was entirely dependent on the intrusion of this secondary state into the normal one seems to throw considerable light on at least one class of hysterical psychosis. Every one of her hypnoses in the evening afforded evidence that the patient was entirely clear and well-ordered in her mind and normal as regards her feeling and volition so long as none of the products of her secondary state was acting as a stimulus 'in the unconscious'. The extremely marked psychosis which appeared whenever there was any considerable interval in this unburdening process showed the degree to which those products influenced the psychical events of her 'normal' state. It is hard to avoid expressing the situation by saying that the patient was split into two personalities of which one was mentally normal and the other insane. The sharp division between the two states in the present patient only exhibits more clearly, in my opinion, what has given rise to a number of unexplained problems in many other hysterical patients. It was especially noticeable in Anna O. how much the products of her 'bad self', as she herself called it, affected her moral habit of mind. If these products had not been continually disposed of, we should have been faced by a hysteric of the malicious type - refractory, lazy, disagreeable and ill-natured; but, as it was, after the removal of those stimuli her true character, which was the opposite of all these, always reappeared at once.

Nevertheless, though her two states were thus sharply separated, not only did the secondary state intrude into the first one, but - and this was at all events frequently true, and even when she was in a very bad condition - a clear-sighted and calm observer sat, as she put it, in a corner of her brain and looked on at all the mad business. This persistence of clear thinking while the psychosis was actually going on found expression in a very curious way. At a time when, after the hysterical phenomena had ceased, the patient was passing through a temporary depression, she brought up a number of childish fears and self-reproaches, and among them the idea that she had not been ill at all and that the whole business had been simulated. Similar observations, as we know, have frequently been made. When a disorder of this kind has cleared up and the two states of consciousness have once more become merged into one, the patients, looking back to the past, see themselves as the single undivided personality which was aware of all the nonsense; they think they could have prevented it if they had wanted to, and thus they feel as though they had done all the mischief deliberately. - It should be added that this normal thinking which persisted during the secondary state must have fluctuated enormously in its amount and must very often have been completely absent.

I have already described the astonishing fact that from beginning to end of the illness all the stimuli arising from the secondary state, together with their consequences, were permanently removed by being given verbal utterance in hypnosis, and I have only to add an assurance that this was not an invention of mine which I imposed on the patient by suggestion. It took me completely by surprise, and not until symptoms had been got rid of in this way in a whole series of instances did I develop a therapeutic technique out of it.

The final cure of the hysteria deserves a few more words. It was accompanied, as I have already said, by considerable disturbances and a deterioration in the patient's mental condition. I had a very strong impression that the numerous products of her secondary state which had been quiescent were now forcing their way into consciousness; and though in the first instance they were being remembered only in her secondary state, they were nevertheless burdening and disturbing her normal one. It remains to be seen whether it may not be that the same origin is to be traced in other cases in which a chronic hysteria terminates in a psychosis.

CASE 2

FRAU EMMY VON N., AGE 40, FROM LIVONIA (Freud)

On May 1, 1889, I took on the case of a lady of about forty years of age, whose symptoms and personality interested me so greatly that I devoted a large part of my time to her and determined to do all I could for her recovery. She was a hysteric and could be put into a state of somnambulism with the greatest ease; and when I became aware of this I decided that I would make use of Breuer's technique of investigation under hypnosis, which I had come to know from the account he had given me of the successful treatment of his first patient. This was my first attempt at handling that therapeutic method. I was still far from having mastered it; in fact I did not carry the analysis of the symptoms far enough nor pursue it systematically enough. I shall perhaps be able best to give a picture of the patient's condition and my medical procedure by reproducing the notes which I made each evening during the first three weeks of the treatment. Wherever later experience has brought me a better understanding, I shall embody it in footnotes and interpolated comments.

May 1, 1889. - This lady, when I first saw her, was lying on a sofa with her head resting on a leather cushion. She still looked young and had finely-cut features, full of character. Her face bore a strained and painful expression, her eyelids were drawn together and her eyes cast down; there was a heavy frown on her forehead and the naso-labial folds were deep. She spoke in a low voice as though with difficulty and her speech was from time to time subject to spastic interruptions amounting to a stammer. She kept her fingers, which exhibited a ceaseless agitation resembling athetosis, tightly clasped together. There were frequent convulsive tic-like movements of her face and the muscles of her neck, during which some of them, especially the right sterno-cleido-mastoid, stood out prominently. Furthermore she frequently interrupted her remarks by producing a curious 'clacking' sound from her mouth which defies imitation.¹

¹ This 'clacking' was made up of a number of sounds. Colleagues of mine with sporting experience told me, on hearing it, that its final notes resembled the call of a capercaillie.

What she told me was perfectly coherent and revealed an unusual degree of education and intelligence. This made it seem all the more strange when every two or three minutes she suddenly broke off, contorted her face into an expression of horror and disgust, stretched out her hand towards me, spreading and crooking her fingers, and exclaimed, in a changed voice, charged with anxiety: 'Keep still! - Don't say anything! - Don't touch me!' She was probably under the influence of some recurrent hallucination of a horrifying kind and was keeping the intruding material at bay with this formula.¹ These interpolations came to an end with equal suddenness and the patient took up what she had been saying, without pursuing her momentary excitement any further, and without explaining or apologizing for her behaviour - probably, therefore, without herself having noticed the interpolation.²

I learned what follows of her circumstances. Her family came from Central Germany, but had been settled for two generations in the Baltic Provinces of Russia, where it possessed large estates. She was one of fourteen children, of which she herself in the thirteenth. Only four of them survive. She was brought up carefully, but under strict discipline by an over-energetic and severe mother. When she was twenty-three she married an extremely gifted and able man who had made a high position for himself as an industrialist on a large scale, but was much older than she was. After a short marriage he died of a stroke. To this event, together with the task of bringing up her two daughters, now sixteen and fourteen years old, who were often ailing and suffered from nervous troubles, she attributed her own illness. Since her husband's death, fourteen years ago, she had been constantly ill with varying degrees of severity. Four years ago her condition was temporarily improved by a course of massage combined with electric baths. Apart from this, all her efforts to regain her health have been unsuccessful. She has travelled a great deal and has many lively interests. She lives at present in a country seat on the Baltic near a large town. For several months she has once more been very ill, suffering from depression and insomnia, and tormented with pains; she went to Abbazia in the vain hope of improvement, and for the last six weeks has been in Vienna, up till now in the care of a physician of outstanding merit.

I suggested that she should separate from the two girls, who had their governess, and go into a nursing home, where I could see her every day. This she agreed to without raising the slightest objection.

¹ These words did in fact represent a protective formula, and this will be explained later on. Since then I have come across similar protective formulas in a melancholic woman who endeavoured by their means to control her tormenting thoughts - wishes that something bad might happen to her husband and her mother, blasphemies, etc.

² What we had here was a hysterical delirium which alternated with normal consciousness, just as a true tic intrudes into a voluntary movement without interfering with it and without being mixed up with it.

On the evening of *May 2* I visited her in the nursing home. I noticed that she started violently whenever the door opened unexpectedly. I therefore arranged that the nurses and the house physicians, when they visited her, should give a loud knock at her door and not enter till she had told them to come in. But even so, she still made a grimace and gave a jump every time anyone entered.

Her chief complaint to-day was of sensations of cold and pain in her left leg which proceeded from her back above the iliac crest. I ordered her to be given warm baths and I shall massage her whole body twice a day.

She is an excellent subject for hypnotism. I had only to hold up a finger in front of her and order her to go to sleep, and she sank back with a dazed and confused look. I suggested that she should sleep well, that all her symptoms should get better, and so on. She heard all this with closed eyes but with unmistakably concentrated attention; and her features gradually relaxed and took on a peaceful appearance. After this first hypnosis she retained a dim memory of my words; but already at the second there was complete somnambulism (with amnesia). I had warned her that I proposed to hypnotize her, to which she raised no difficulty. She has not previously been hypnotized, but it is safe to suppose that she has read about hypnotism, though I cannot tell what notions she may have about the hypnotic state.¹

This treatment by warm baths, massage twice a day and hypnotic suggestion was continued for the next few days. She slept well, got visibly better, and passed most of the day lying quietly in bed. She was not forbidden to see her children, to read, or to deal with her correspondence.

¹ Every time she woke from hypnosis she looked about her for a moment in a confused way, let her eyes fall on me, seemed to have come to her senses, put on her glasses, which she took off before going to sleep, and then became quite lively and on the spot. Although in the course of the treatment (which lasted for seven weeks in this first year and eight in the second) we discussed every sort of subject, and although I put her to sleep twice almost every day, she never made any comment to me about the hypnosis or asked me a single question about it; and in her waking state she seemed, so far as possible, to ignore the fact that she was undergoing hypnotic treatment.

May 8, morning. - She entertained me, in an apparently quite normal state, with gruesome stories about animals. She had read in the *Frankfurter Zeitung*, which lay on the table in front of her, a story of how an apprentice had tied up a boy and put a white mouse into his mouth. The boy had died of fright. Dr. K. had told her that he had sent a whole case of white rats to Tiflis. As she told me this she demonstrated every sign of horror. She clenched and unclenched her hand several times. 'Keep still! - Don't say anything! - Don't touch me! - Supposing a creature like that was in the bed!' (She shuddered.) 'Only think, when it's unpacked! There's a dead rat in among them - one that's been gn-aw-aw-ed at!'

During the hypnosis I tried to disperse these animal hallucinations. While she was asleep I picked up the *Frankfurter Zeitung*. I found the anecdote about the boy being maltreated, but without any reference to mice or rats. So she had introduced these from her delirium while she was reading. (I told her in the evening of our conversation about the white mice. She knew nothing of it, was very much astonished and laughed heartily.¹)

¹ A sudden interpolation like this of a delirium into a waking state was not uncommon with her and was often repeated later in my presence. She used to complain that in conversation she often gave the most absurd answers, so that people did not understand her. On the occasion when I first visited her I asked her how old she was and she answered quite seriously: 'I am a woman dating from last century.' Some weeks later she explained to me she had been thinking at the time in her delirium of a beautiful old cupboard which, as a connoisseur of old furniture, she had bought in the course of her travels. It was to this cupboard that her answer had referred when my question about her age raised the topic of dates.

During the afternoon she had what she called a 'neck cramp',¹ which, however, as she said, 'only lasted a short time - a couple of hours'.

Evening. - I requested her, under hypnosis, to talk, which, after some effort, she succeeded in doing. She spoke softly and reflected for a moment each time before answering. Her expression altered according to the subject of her remarks, and grew calm as soon as my suggestion had put an end to the impression made upon her by what she was saying. I asked her why it was that she was so easily frightened, and she answered: 'It has to do with memories of my earliest youth.' 'When?' 'First when I was five years old and my brothers and sisters often threw dead animals at me. That was when I had my first fainting fit and spasms. But my aunt said it was disgraceful and that I ought not to have attacks like that, and so they stopped. Then I was frightened again when I was seven and I unexpectedly saw my sister in her coffin; and again when I was eight and my brother terrified me so often by dressing up in sheets like a ghost; and again when I was nine and I saw my aunt in her coffin and her jaw suddenly dropped.'

This series of traumatic precipitating causes which she produced in answer to my question why she was so liable to fright was clearly ready to hand in her memory. She could not have collected these episodes from different periods of her childhood so quickly during the short interval which elapsed between my question and her answer. At the end of each separate story she twitched all over and took on a look of fear and horror. At the end of the last one she opened her mouth wide and panted for breath. The words in which she described the terrifying subject-matter of her experience were pronounced with difficulty and between gasps. Afterwards her features became peaceful.

¹ A species of migraine.

In reply to a question she told me that while she was describing these scenes she saw them before her, in a plastic form, and in their natural colours. She said that in general she thought of these experiences very often and had done so in the last few days. Whenever this happened she saw these scenes with all the vividness of reality.¹ I now understand why she entertains me so often with animal scenes and pictures of corpses. My therapy consists in wiping away these pictures, so that she is no longer able to see them before her. To give support to my suggestion I stroked her several times over the eyes.

May 9. - Without my having given her any further suggestion, she had slept well. But she had gastric pains in the morning. They came on yesterday in the garden where, she stayed out too long with her children. She agreed to my limiting the children's visits to two and a half hours. A few days ago she had reproached herself for leaving the children by themselves. I found her in a somewhat excited state to-day; her forehead was lined, her speech was halting and she made her clacking noises. While she was being massaged she told me only that the children's governess had brought her an ethnological atlas and that some pictures in it of American Indians dressed up as animals had given her a great shock. 'Only think, if they came to life!' (She shuddered.)

¹ Many other hysterical patients have reported to us that they have memories of this kind in vivid visual pictures and that this applied especially to their pathogenic memories.

Under hypnosis I asked why she had been so much frightened by these pictures, since she was no longer afraid of animals. She said they had reminded her of visions she had had (when she was nineteen) at the time of her brother's death. (I shall hold over enquiring into this memory until later.) I then asked her whether she had always spoken with a stammer and how long she had had her *tic* (the peculiar clacking sound).¹ Her stammering, she said, had come on while she was ill; she had had the *tic* for the last five years, ever since a time when she this was sitting by the bedside of her younger daughter who was very ill, and had wanted to keep absolutely *quiet*. I tried to reduce the importance of this memory, by pointing out that after all nothing had happened to her daughter, and so on. The thing came on, she said, whenever she was apprehensive or frightened. I instructed her not to be frightened of the pictures of the Red Indians but to laugh heartily at them and even to draw my attention to them. And this did in fact happen after she had woken up: she looked at the book, asked whether I had seen it, opened it at the page and laughed out loud at the grotesque figures, without a trace of fear and without any strain in her features. Dr. Breuer came in suddenly with the house-physician to visit her. She was frightened and began to make her clacking noise, so that they soon left us. She explained that she was so much agitated because she was unpleasantly affected by the fact that the house-physician came in every time as well.

I had also got rid of her gastric pains during the hypnosis by stroking her, and I told her that though she would expect the pain to return after her midday meal it would not do so.

Evening. - For the first time she was cheerful and talkative and gave evidence of a sense of humour that I should not have expected in such a serious woman; and, among other things, in the strong feeling that she was better, she made fun of her treatment by my medical predecessor. She had long intended, she said, to give up that treatment but had not been able to find the right method of doing so till a chance remark made by Dr. Breuer, when he visited her once, showed her a way out. When I seemed to be surprised at this, she grew frightened and began to blame herself very severely for having been indiscreet. But I was able, it seemed, to re-assure her. - She had had no gastric pains, though she had expected them.

¹ I had already asked her this question about the *tic* during her waking state, and she had replied: 'I don't know; oh, a very long time.'

Under hypnosis I asked her to tell me further experiences which had given her a lasting fright. She produced a second series of this kind, dating from her later youth, with as much promptitude as the first series and she assured me once more that all these scenes appeared before her often, vividly and in colours. One of them was of how she saw a female cousin taken off to an insane asylum (when she was fifteen). She tried to call for help but was unable to, and lost her power of speech till the evening of the same day. Since she talked so often about asylums in her waking state, I interrupted her and asked on what other occasions she had been concerned with insanity. She told me that her mother had herself been in an asylum for some time. They had once had a maid-servant one of whose previous mistresses had spent a long time in an asylum and who used to tell her horrifying stories of how the patients were tied to chairs, beaten, and so on. As she told me this she clenched her hands in horror; she saw all this before her eyes. I endeavoured to correct her ideas about insane asylums, and assured her that she would be able to hear about institutions of this kind without referring them to herself. At this, her features relaxed.

She continued her list of terrifying memories. One, at fifteen, of how she found her mother, who had had a stroke, lying on the floor (her mother lived for another four years); again, at nineteen, how she came home one day and found her mother dead, with a distorted face. I naturally had considerable difficulty in mitigating these memories. After a rather lengthy explanation, I assured her that this picture, too, would only appear to her again indistinctly and without strength. - Another memory was how, at nineteen, she lifted up a stone and found a toad under it, which made her lose her power of speech for hours afterwards.¹

During this hypnosis I convinced myself that she knew everything that happened in the last hypnosis, whereas in waking life she knows nothing of it.

¹ A special kind of symbolism must, no doubt, have lain behind the toad, but I unfortunately neglected to enquire into it.

May 10, morning. - For the first time to-day she was given a bran bath instead of her usual warm bath. I found her looking cross and with a pinched face, with her hands wrapped in a shawl. She complained of cold and pains. When I asked her what was the matter, she told me that the bath had been uncomfortably short to sit in and had brought on pains. During the massage she started by saying that she still felt badly about having given Dr. Breuer away yesterday. I pacified her with a white lie and said that I had known about it all along, where upon her agitation (clacking, grimaces) ceased. So each time even while I am massaging her, my influence has already begun to affect her; she grows quieter and clearer in the head, and even without questioning under hypnosis can discover the cause of her ill-humour on that day. Nor is her conversation during the massage so aimless as would appear. On the contrary, it contains a fairly complete reproduction of the memories and new impressions which have affected her since our last talk, and it often leads on, in a quite unexpected way, to pathogenic reminiscences of which she unburdens herself without being asked to. It is as though she had adopted my procedure and was making use of our conversation, apparently unconstrained and guided by chance, as a supplement to her hypnosis. For instance, to-day she began talking about her family, and in a very roundabout way got on to the subject of a cousin. He was rather queer in the head and his parents had all his teeth pulled out at one sitting. She accompanied the story with horrified looks and kept repeating her protective formula ('Keep still! - Don't say anything! - Don't touch me!'). After this her face smoothed out and she became cheerful. Thus, her behaviour in waking life is directed by the experiences she has had during her somnambulism, in spite of her believing, while she is awake, that she knows nothing about them.

Under hypnosis I repeated my question as to what it was that had made her upset and I got the same answers but in the reverse order: (1) her indiscreet talk yesterday, and (2) her pains caused by her being so uncomfortable in the bath. - I asked her to-day the meaning of her phrase 'Keep still!', etc. She explained that when she had frightening thoughts she was afraid of their being interrupted in their course, because then everything would get confused and things would be even worse. The 'Keep still!' related to the fact that the animal shapes which appeared to her when she was in a bad state started moving and began to attack her if anyone made a movement in her presence. The final injunction 'Don't touch me!' was derived from the following experiences. She told me how, when her brother had been so ill from taking a lot of morphine - she was nineteen at the time- he used often to seize hold of her; and how, another time, an acquaintance had suddenly gone mad in the house and had caught her by the arm; (there was a third, similar instance, which she did not remember exactly; and lastly, how, when she was twenty-eight and her daughter was very ill, the child had caught hold of her so forcibly, in its delirium that she was almost choked. Though these four instances were so widely separated in time, she told me them in a single sentence and in such rapid succession that they might have been a single episode in four acts. Incidentally, all the accounts she gave of traumas arranged like these in groups began with a 'how', the component traumas being separated by an 'and'. Since I noticed that the protective formula was designed to safeguard her against a recurrence of such experiences, I removed this fear by suggestion, and in fact I never heard the formula from her again.

Evening. - I found her very cheerful. She told me, with a laugh, that she had been frightened by a small dog which barked at her in the garden. Her face was a little bit drawn, however, and there was some internal agitation which did not disappear until she had asked me whether I was annoyed by something she had said during the massage this morning and I had said 'no'. Her period began again to-day after an interval of scarcely a fortnight. I promised to regulate this by hypnotic suggestion and, under hypnosis, set the interval at 28 days.¹

Under hypnosis, I also asked her whether she remembered the last thing she told me; in asking this what I had in mind was a task which had been left over from yesterday evening; but she began quite correctly with the 'don't touch me' from *this morning's* hypnosis. So I took her back to yesterday's topic. I had asked her the origin of her stammering and she had replied, 'I don't know'.² I had therefore requested her to remember it by the time of to-day's hypnosis. She accordingly answered me to-day without any further reflection but in great agitation and with spastic impediments to her speech: 'How the horses bolted once with the children in the carriage; and how another time I was driving through the forest with the children in a thunderstorm, and a tree just in front of the horses was struck by lightning and the horses shied and I thought: "You must keep quite still now, or your screaming will frighten the horses even more and the coachman won't be able to hold them in at all." It came on from that moment.' She was quite unusually excited as she told me this story. I further learnt from her that the stammer had begun immediately after the first of these two occasions, but had disappeared shortly afterwards and then came on for good after the second, similar occasion. I extinguished her plastic memory of these scenes, but asked her to imagine them once more. She appeared to try to do this and remained quiet as she did so; and from now on she spoke in the hypnosis without any spastic impediment.³

¹ A suggestion which was carried out.

² It is possible that this answer, 'I don't know', was correct; but it may quite as well have indicated reluctance to talk about the causes of the stammering. I have since observed in other patients that the greater the effort they have made to repress a thing from their consciousness the more difficulty they have in remembering it under hypnosis as well as in waking life.

³ As we see from this, the patient's *tic*-like clacking and her spastic stammer were two symptoms which went back to similar precipitating causes and had an analogous mechanism. I have already commented on this mechanism in a short paper on hypnotic treatment (1892-3b), and I shall also return to it below.

Finding her disposed to be communicative, I asked her what further events in her life had frightened her so much that they had left her with plastic memories. She replied by giving me a collection of such experiences:- How a year after her mother's death, she was visiting a Frenchwoman who was a friend of hers, and had been sent into the next room with another girl to fetch a dictionary, and had then seen someone sit up in the bed who looked exactly like the woman she had just left behind in the other room. She went stiff all over and was rooted to the spot. She learnt afterwards that it was a specially arranged dummy. I said that what she saw had been a hallucination, and appealed to her good sense, and her face relaxed. How she had nursed her sick brother and he had had such fearful attacks as a result of the morphine and had terrified her and seized hold of her. I remembered that she had already mentioned this experience this morning, and, as an experiment, I asked her on what other occasions this 'seizing hold' had happened. To my agreeable surprise she made a long pause this time before answering and then asked doubtfully 'My little girl?' She was quite unable to recall the other two occasions (see above). My prohibition - my expunging of her memories - had therefore been effective. - Further, how, while she was nursing her brother, her aunt's pale face had suddenly appeared over the top of the screen. She had come to convert him to Catholicism.

I saw that I had come to the root of her constant fear of surprises, and I asked for further instances of this. She went on: How they had a friend staying at her home who liked slipping into the room very softly so that all of a sudden he was there; how she had been so ill after her mother's death and had gone to a health resort and a lunatic had walked into her room several times at night by mistake and come right up to her bed; and lastly, how, on the journey here from Abbazia a strange man had four times opened the door of her compartment suddenly and had fixed his eyes on her each time with a stare. She was so much terrified that she sent for the conductor.

I wiped out all these memories, woke her up and assured her she would sleep well to-night, having omitted to give her this suggestion in her hypnosis. The improvement of her general condition was shown by her remark that she had not done any reading to-day, she was living in such a happy dream - she, who always had to be doing something because of her inner unrest.

May 11, morning. - To-day she had an appointment with Dr. N., the gynaecologist, who is to examine her elder daughter about her menstrual troubles. I found Frau Emmy in a rather disturbed state, though this was expressed in slighter physical signs than formerly. She called out from time to time: 'I'm afraid, so afraid, I think I shall die.' I asked her what she was afraid of? Was it of Dr. N.? She did not know, she said; she was just afraid. Under hypnosis, which I induced before my colleague arrived, she declared that she was afraid she had offended me by something she had said during the massage yesterday which seemed to her to have been impolite. She was frightened of anything new, too, and consequently of the new doctor. I was able to soothe her, and though she started once or twice in the presence of Dr. N., she behaved very well apart from this and produced neither her clacking noises nor any inhibition of speech. After he had gone I put her under hypnosis once more, to remove any possible residue of the excitement caused by his visit. She herself was very much pleased with her behaviour and put great hopes in the treatment; and I tried to convince her from this example that there is no need to be afraid of what is new, since it also contains what is good.¹

¹ Didactic suggestions of this kind always missed fire with Frau Emmy, as will be seen from what follows.

Evening. - She was very lively and unburdened herself of a number of doubts and scruples during our conversation before the hypnosis. Under hypnosis I asked her what event in her life had produced the most lasting effect on her and came up most often in her memory. Her husband's death, she said. I got her to describe this event to me in full detail, and this she did with every sign of deepest emotion but without any clacking or stammering: - How, she began, they had been at a place on the Riviera of which they were both very fond, and while they were crossing a bridge he had suddenly sunk to the ground and lain there lifeless for a few minutes but had then got up again and seemed quite well; how, a short time afterwards, as she was lying in bed after her second confinement, her husband, who had been sitting at breakfast at a small table beside her bed, reading a newspaper, had got up all at once, looked at her so strangely, taken a few paces forward and then fallen down dead; she had got out of bed, and the doctors who were called in had made efforts to revive him which she had heard from the next room; but it had been in vain. And, she then went on to say, how the baby, which was then a few weeks old, had been seized with a serious illness which had lasted for six months, during which she herself had been in bed with a high fever. - And there now followed in chronological order her grievances against this child, which she threw out rapidly with an angry look on her face, in the way one would speak of someone who had become a nuisance. This child, she said, had been very queer for a long time; it had screamed all the time and did not sleep, and it had developed a paralysis of the left leg which there had seemed very little hope of curing. When it was four it had had visions; it had been late in learning to walk and to talk, so that for a long time it had been believed to be imbecile. According to the doctors it had had encephalitis and inflammation of the spinal cord and she did not know what else besides. I interrupted her here and pointed out to her that this same child was to-day a normal girl and in the bloom of health, and I made it impossible for her to see any of these melancholy things again, not only by wiping out her memories of them in their *plastic* form but by removing her whole recollection of them, as though they had never been present in her mind. I promised her that this would lead to her being freed from the expectation of misfortune which perpetually tormented her and from the pains all over her body, of which she had been complaining precisely during her narrative, after we had heard nothing of them for several days.¹

¹ On this occasion my energy seems to have carried me too far. When, as much as eighteen months later, I saw Frau Emmy again in a relatively good state of health, she complained that there were a number of most important moments in her life of which she had only the vaguest memory. She regarded this as evidence of a weakening of her memory, and I had to be careful not to tell her the cause of this particular instance of amnesia. - The overwhelming success of the treatment in this respect was no doubt also due to the great detail in which I had got her to repeat these memories to me (in far greater detail than is shown in my notes), whereas with other memories I was too often satisfied with a mere mention.

To my surprise, after this suggestion of mine, she began without any transition speaking of Prince L., whose escape from an asylum was being talked about a great deal at the time. She brought out new fears about asylums - that people in them were treated with douches of ice-cold water on the head and put into an apparatus which turned them round and round till they were quiet. When, three days ago, she had first complained about her fear of asylums, I had interrupted her after her first story, that the patients were tied on to chairs. I now saw that I had gained nothing by this interruption and that I cannot evade listening to her stories in every detail to the very end. After these arrears had been made up, I took this fresh crop of fears from her as well, I appealed to her good sense and told her she really ought to believe me more than the silly girl from whom she had had the gruesome stories about the way in which asylums are run. As I noticed that she still stammered occasionally in telling me these further things, I asked her once more what the stammer came from. No reply. 'Don't you know?' 'No.' 'Why not?' 'Why not? Because I *mayn't!*' (She pronounced these words violently and angrily.) This declaration seemed to me to be evidence of the success of my suggestion, but she expressed a desire for me to wake her up from her hypnosis, and I did so.¹

¹ It was not until the next day that I understood this little scene. Her unruly nature, which rebelled, both in her waking state and in artificial sleep, against any constraint, had made her angry with me because I had assumed that her narrative was finished and had interrupted it by my concluding suggestion. I have come across many other proofs that she kept a critical eye upon my work in her hypnotic consciousness. She had probably wanted to reproach me with interrupting her story to-day just as I had previously interrupted her accounts of the horrors in the asylum; but she had not ventured to do so. Instead of this, she had produced these further stories, apparently without any transition and without revealing the connecting thoughts. My blunder was made plain to me the next day by a depreciatory comment on her part.

May 12. - Contrary to my expectation, she had slept badly and only for a short time. I found her in a state of great anxiety, though, incidentally, without showing her usual physical signs of it. She would not say what the matter was, but only that she had had bad dreams and kept seeing the same things. 'How dreadful it would be,' she said, 'if they were to come to life.' During the massage she dealt with a few points in reply to questions. She then became cheerful; she told me about her social life at her dower house on the Baltic, of the important people whom she entertains from the neighbouring town, and so on.

Hypnosis. - She had had some fearful dreams. The legs and arms of the chairs were all turned into snakes; a monster with a vulture's beak was tearing and eating at her all over her body; other wild animals leapt upon her, etc. She then passed on to other animal-deliria, which, however, she qualified with the addition 'That was real' (not a dream): how (on an earlier occasion) she had been going to pick up a ball of wool, and it was a mouse and ran away; how she had been on a walk, and a big toad suddenly jumped out at her, and so on. I saw that my general prohibition had been ineffective and that I should have to take her frightening impressions away from her one by one.¹ I took an opportunity of asking her, too, why she had gastric pains and what they came from. (I believe that all her attacks of zoöpsia are accompanied by gastric pains.) Her answer, which she gave rather grudgingly, was that she did not know. I requested her to remember by tomorrow. She then said in a definitely grumbling tone that I was not to keep on asking her where this and that came from, but to let her tell me what she had to say, I fell in with this, and she went on without preface: 'When they carried him out, I could not believe he was dead.' (So she was talking of her husband again, and I saw now that the cause of her ill-humour was that she had been suffering from the residues of this story which had been kept back.) After this, she said, she had hated her child for three years, because she always told herself that she might have been able to nurse her husband back to health if she had not been in bed on account of the child. And then after her husband's death there had been nothing but insults and agitations. His relatives, who had always been against the marriage and had then been angry because they had been so happy together, had spread a rumour that she had poisoned him, so that she had wanted to demand an enquiry. Her relatives had involved her in all kinds of legal proceedings with the help of a shady journalist. The wretch had sent round agents to stir people up against her. He got the local papers to print libellous articles about her, and then sent her the cuttings. This had been the origin of her unsociability and her hatred of all strangers. After I had spoken some calming words about what she had told me, she said she felt easier.

¹ I unfortunately failed to enquire into the significance of Frau Emmy's animal visions - to distinguish, for instance, what was symbolic in her fear of animals from what was primary horror, such as is characteristic of many neuropaths from youth onwards.

May 13. - Once again she had slept badly, owing to gastric pains. She had not eaten any supper. She also complained of pains in her right arm. But she was in a good mood; she was cheerful, and, since yesterday, has treated me with special distinction. She asked me my opinion about all sorts of things that seemed to her important, and became quite unreasonably agitated, for instance, when I had to look for the towels needed in massage, and so on. Her clacking and facial *tic* were frequent.

Hypnosis. - Yesterday evening it had suddenly occurred to her why the small animals she saw grew so enormous. It happened to her for the first time at D-- during a theatrical performance in which a huge lizard appeared on the stage. This memory had tormented her a great deal yesterday as well.¹

¹ The visual memory of the big lizard had no doubt only attained its great importance owing to its coinciding in time with a powerful affect which she must have experienced during the theatrical performance. In treating the present patient, as I have already confessed, I was often content to receive the most superficial explanations. In this instance, too, I failed to make any further investigation. - We shall be reminded, moreover, of hysterical macropsia. Frau Emmy was extremely short-sighted and astigmatic, and her hallucinations may often have been provoked by the indistinctness of her visual perceptions.

The reason for the re-appearance of the clacking was that yesterday she had abdominal pains and had tried not to show it by groaning. She knew nothing of the true precipitating cause of the clacking (see above). She remembered, too, that I had instructed her to discover the origin of her gastric pains. She did not know it, however, and asked me to help her. I asked whether, perhaps, on some occasion after a great excitement, she had forced herself to eat. She confirmed this. After her husband's death she had for a long time lost her appetite completely and had only eaten from a sense of duty; and her gastric pains had in fact begun at that time. I then removed her gastric pains by stroking her a few times across the epigastrium. She then began of her own accord to talk about the things that had most affected her. 'I have told you,' she said, 'that I was not fond of the child. But I ought to add that one could not have guessed it from my behaviour. I did everything that was necessary. Even now I reproach myself for being fonder of the elder one.'

May 14. - She was well and cheerful and had slept till 7.30 this morning. She only complained of slight pains in the radial region of her hand and in her head and face. What she tells me before the hypnosis becomes more and more significant. To-day she had scarcely anything dreadful to produce. She complained of pains and loss of sensation in her right leg. She told me that she had had an attack of abdominal inflammation in 1871; when she had hardly recovered from this, she had nursed her sick brother, and it was then that the pains first came on. They had even led to a temporary paralysis of her right leg.

During the hypnosis I asked her whether it would now be possible for her to take part in social life or whether she was still too much afraid. She said it was still disagreeable to have anyone standing behind her or just beside her. In this connection she told me of some more occasions on which she had been disagreeably surprised by someone suddenly appearing. Once, for instance, when she had been going for a walk with her daughters on the island of Rügen, two suspicious-looking individuals had come out from some bushes and insulted them. In Abbazia, while she was out for a walk one evening, a beggar had suddenly emerged from behind a rock and had knelt down in front of her. It seems that he was a harmless lunatic. Lastly, she told me of how her isolated country house had been broken into at night, which had very much alarmed her. It is easy to see, however, that the essential origin of this fear of people was the persecution to which she had been subjected after her husband's death.¹

Evening. - Though she appeared to be in high spirits, she greeted me with the exclamation: 'I'm frightened to death; oh, I can hardly tell you, I hate myself!' I learned at last that she had had a visit from Dr. Breuer and that on his appearance she had given a start of alarm. As he noticed it, she had assured him that it was 'only this once'. She felt so very sorry on my account that she should have had to betray this relic of her former nervousness. I have more than once had occasion to notice during these last few days how hard she is on herself, how liable she is to blame herself severely for the least signs of neglect if the towels for the massage are not in their usual place or if the newspaper for me to read when she is asleep is not instantly ready to hand. After the removal of the first and most superficial layer of tormenting recollections, her morally oversensitive personality, with its tendency to self-depreciation, has come into view. Both in her waking state and under hypnosis, I duly told her (what amounted to the old legal tag '*de minimis non curat lex*') that there is a whole multitude of indifferent, small things lying between what is good and what is evil - things about which no one need reproach himself. She did not take in my lesson, I fancy, any more than would an ascetic mediaeval monk, who sees the finger of God or a temptation of the Devil in every trivial event of his life and who is incapable of picturing the world even for a brief moment or in its smallest corner as being without reference to himself.

In her hypnosis she brought up some further horrifying images (in Abbazia, for instance, she saw bloody heads on every wave of the sea). I made her repeat the lessons I had given her while she was awake.

¹ At the time I wrote this I was inclined to look for a *psychical* origin for all symptoms in cases of hysteria. I should now explain this sexually abstinent woman's tendency to anxiety as being due to *neurosis* (i.e. anxiety neurosis).

May 15. - She had slept till 8.30 a.m. but had become restless towards morning, and received me with some slight signs of her *tic*, clacking and speech-inhibition. 'I'm frightened to death,' she said once more. In reply to a question she told me that the Pension in which her children were staying was on the fourth floor of a building and reached by a lift. She had insisted yesterday that the children should make use of the lift for coming down as well as going up, and was now reproaching herself about this, because the lift was not entirely to be trusted. The owner of the Pension had said so himself. Had I heard, she asked, the story of the Countess Sch. who had been killed in Rome in an accident of that kind? I happen to be acquainted with the Pension and I know that the lift is the private property of the owner of the Pension; it does not seem to me very likely that this man, who makes a special point of the lift in an advertisement, would himself have warned anyone against using it. It seemed to me that we had here one of the paramnesias that are brought about by anxiety. I told her my view and succeeded without any difficulty in getting her herself to laugh at the improbability of her fears. For that very reason I could not believe that this was the cause of her anxiety and determined to put the question to her hypnotic consciousness. During massage, which I resumed to-day after a few days' interval, she told me a loosely connected string of anecdotes, which may have been true - about a toad which was found in a cellar, an eccentric mother who looked after her idiot child in a strange fashion, a woman who was shut up in an asylum because she had melancholia - and which showed the kind of recollections that passed through her head when she was in a disquieted frame of mind. When she had got these stories out she became very cheerful. She described her life on her estate and her contacts with prominent men in German Russia and North Germany; and I really found it extremely hard to reconcile activities of this kind with the picture of such a severely neurotic woman.

I therefore asked her in hypnosis why she was so restless this morning. In place of her doubts about the lift, she informed me that she had been afraid that her period was going to start again and would again interfere with the massage.¹

¹ The sequence of events had accordingly been as follows: when she woke up in the morning she found herself in an anxious mood, and to account for it she grasped at the first anxious idea that came to mind. On the previous afternoon she had had a conversation about the lift at the Pension. Over-careful of her children as usual, she had asked their governess whether her elder daughter, who could not walk much on account of ovarian neuralgia on the right side and pains in the right leg, used the lift for going down as well as up. A paramnesia then enabled her to link the anxiety she was conscious of with the idea of the lift. Her consciousness did not present her with the *real* cause of her anxiety; *that* only emerged - but now it did so without any hesitation - when I questioned her about it in hypnosis. The process was the same as that studied by Bernheim and others after him in persons who carry out in a post-hypnotic condition instructions given them during hypnosis. For instance, Bernheim (1886, 29) suggested to a patient that after he woke up he should put both his thumbs in his mouth. He did so, and excused his action by saying that his tongue had been giving him pain since the previous day when he had bitten it in an epileptiform attack. Again, in obedience to a suggestion, a girl made an attempt to murder a law-court officer who was totally unknown to her. When she was seized and questioned as to the motives of her act, she invented a story of a wrong done to her which called for revenge. There seems to be a necessity for bringing psychical phenomena of which one becomes conscious into causal connection with other conscious material. In cases in which the true causation evades conscious perception one does not hesitate to attempt to make another connection, which one believes, although it is false. It is clear that a split in the content of consciousness must greatly facilitate the occurrence of 'false connections' of this kind.

I shall dwell a little on this example I have given of a false connection, since in more than one respect it deserves to be described as typical. It is typical, in the first place, of the present patient's behaviour; for in the further course of the treatment she afforded me many opportunities of resolving such false connections by explanations arrived at in hypnosis, and of removing their effects. I will give a detailed account of one of these instances, since it throws a strong light on the psychological phenomenon in question. I had recommended Frau Emmy to try replacing her usual luke-warm bath by a hip-bath of cool water, which I told her would be more refreshing. She used to obey medical instructions implicitly, but never ceased to view them with profound mistrust. I have already said that she had hardly ever derived any benefit from her medical treatment. My advice to her to take cool baths was not delivered in such an authoritative manner as to prevent her from having the courage to give open expression to her hesitations: 'Whenever I have taken a cool bath,' she said, 'it has made me melancholy for the rest of the day. But I will try it again, if you like; you mustn't think I won't do whatever you tell me to.' I pretended to give up my proposal, but in her next hypnosis I suggested to her that she should herself put forward the idea of cool baths - having thought it over, she would like to try the experiment after all, and so on. This in fact happened. Next day, she took up the idea of having cool hip-baths; she tried to convince me with all the arguments which I had previously used to her, and I agreed without much enthusiasm. But on the day after she had had the hip-bath I did in fact find her in a deep depression. 'Why are you like this to-day?' I asked. 'I knew beforehand that it would happen,' she answered, 'it's because of the cold bath; it always happens.' 'It was you yourself who asked for it,' I said. 'Now we know they don't suit you. We'll go back to the luke-warm ones.' Afterwards I asked her in her hypnosis, 'Was it really the cool bath that depressed you so much?' 'Oh,' was her answer, 'the cool bath had nothing to do with it. But I read in the paper this morning that a revolution had broken out in San Domingo. Whenever there is any unrest there the whites are always the sufferers; and I have a brother in San Domingo who has already caused us a lot of concern, and I am worried now in case something happens to him.' This brought to a close the issue between us. Next morning she took her cool hip-bath as though it were a matter of course and continued doing so for several weeks without ever attributing any depression to that source.

It will be agreed that this instance is typical also of the behaviour of a large number of neuropaths in regard to the therapeutic procedures recommended by their physicians. The patient who develops a symptom on a particular day - whether owing to unrest in San Domingo or else where - is always inclined to attribute it to his doctor's latest advice. Of the two conditions necessary for bringing about a false connection of this kind, one, mistrust, seems always to be present; while the other, the splitting of consciousness, is replaced by the fact that most neuropaths have in part no knowledge of the true causes (or at any rate the releasing causes) of their disorder, and in part deliberately avoid such knowledge, because they are unwilling to be reminded of that share of the causes for which they themselves are to blame.

It might be thought that these psychical conditions which we have laid down for neuropaths as distinct from hysterics - namely, ignorance or deliberate overlooking - would necessarily be more favourable for the production of a false connection than would be the presence of a split in consciousness, which, after all, withdraws material for causal connections from consciousness. The split, however, is rarely a clear cut one. As a rule, portions of the subconscious complex of ideas intrude into the subject's ordinary consciousness, and it is precisely they that provoke this kind of disturbance. What is usually perceived consciously, as in the instances I have quoted above, is the general feeling attached to the complex - a mood of anxiety, it may be, or of grief; and it is this feeling that, by a kind of 'compulsion to associate', must have a connection found for it with some complex of ideas which is present in consciousness. (Compare, too, the mechanism of obsessional ideas, described in two papers, 1894a and 1895c.)

Not long ago I was able to convince myself of the strength of a compulsion of this kind towards association from some observations made in a different field. For several weeks I found myself obliged to exchange my usual bed for a harder one, in which I had more numerous or more vivid dreams, or in which, it may be, I was unable to reach the normal depth of sleep. In the first quarter of an hour after waking I remembered all the dreams I had had during the night, and I

Studies On Hysteria

took the trouble to write them down and try to solve them. I succeeded in tracing all these dreams back to two factors: (1) to the necessity for working out any ideas which I had only dwelt upon cursorily during the day - which had only been touched upon and not finally dealt with; and (2) to the compulsion to link together any ideas that might be present in the same state of consciousness. The senseless and contradictory character of the dreams could be traced back to the uncontrolled ascendancy of this latter factor.

It is a quite regular thing for the mood attaching to an experience and the subject-matter of that experience to come into different relations to the primary consciousness. This was shown in the case of another patient, Frau Cäcilie M., whom I got to know far more thoroughly than any of the other patients mentioned in these studies. I collected from her very numerous and convincing proofs of the existence of a psychical mechanism of hysterical phenomena such as I have put forward above. Personal considerations unfortunately make it impossible for me to give a detailed case history of this patient, though I shall have occasion to refer to it from time to time. Frau Cäcilie had latterly been in a peculiar hysterical state. This state was certainly not a unique one, though I do not know if it has hitherto been recognized. It might be called a 'hysterical psychosis for the payment of old debts'. The patient had experienced numerous psychical traumas and had spent many years in a chronic hysteria which was attended by a great variety of manifestations. The causes of all these states of hers were unknown to her and everyone else. Her remarkably well-stocked memory showed the most striking gaps. She herself complained that it was as though her life was chopped in pieces. One day an old memory suddenly broke in upon her clear and tangible and with all the freshness of a new sensation. For nearly three years after this she once again lived through all the traumas of her life - long-forgotten, as they seemed to her, and some, indeed, never remembered at all - accompanied by the acutest suffering and by the return of all the symptoms she had ever had. The 'old debts' which were thus paid covered a period of thirty-three years and made it possible to discover the origins, often very complicated, of all her abnormal states. The only way of relieving her was to give her an opportunity of talking off under hypnosis the particular reminiscence which was tormenting her at the moment, together with all its accompanying load of feelings and their physical expression. When I was prevented from doing so, so that she was obliged to say these things to a person in whose presence she felt embarrassed, it sometimes happened that she would tell him her story quite calmly and would subsequently, in hypnosis, produce for me all the tears, all the expressions of despair, with which she would have wished to accompany her recital. For a few hours after a purgation of this kind during hypnosis she used to be quite well and on the spot. After a short interval the next reminiscence of the series would break its way in. But this reminiscence would be preceded some hours earlier by the mood which was proper to it. She would become anxious or irritable or despairing without ever suspecting that this mood did not belong to the present moment but to the state to which she would next be subject. During this transition period she would habitually make a false connection to which she would obstinately cling until her next hypnosis. For instance, she once greeted me with the question: 'Am I not a worthless person? Is it not a sign of worthlessness that I said to you what I did yesterday?' What she had actually said to me the day before did not in fact seem to me to justify this damning verdict. After a short discussion, she clearly recognized this; but her next hypnosis brought to light a recollection of an occasion, twelve years earlier, which had aroused severe self-reproaches in her - though, incidentally, she no longer subscribed to them in the least.

I then got her to tell me the history of her pains in the leg. She began in the same way as yesterday and then went on with a long series of instances of experiences, alternately distressing and irritating, which she had had at the same time as her pains in the leg and the effect of which had each time been to make them worse, even to the point of her having bilateral paralysis of the legs with loss of sensation in them. The same was true of the pains in her arm. They too had come on while she was nursing someone who was ill, at the same time as the 'neck-cramps'. Concerning the latter, I only learnt that they succeeded some curious restless states accompanied by depression which had been there previously. They consist in an 'icy grip' on the back of the neck, together with an onset of rigidity and a painful coldness in all her extremities, an incapacity to speak and complete prostration. They last from six to twelve hours. My attempts to show that this complex of symptoms represented a recollection failed. I put some questions to her with a view to discovering whether her brother, while she was nursing him during his delirium, had ever caught hold of her by the neck; but she denied this. She said she did not know where these attacks came from.¹

¹ On subsequent reflection, I cannot help thinking that these 'neck cramps' may have been determined organically and have been analogous to migraine. In medical practice we come across a number of conditions of this kind which have not been described. These show such a striking resemblance to the classical attack of hemicrania that we are tempted to extend the concept of the latter and to attach only secondary importance to the localization of the pain. As we know, many neuropathic women very often have hysterical attacks (spasms and deliria) along with an attack of migraine. Every time I observed a 'neck-cramp' in Frau Emmy it was accompanied by an attack of delirium.

As regards the pains in her arm and leg, I am of opinion that what we have here is the not very interesting and correspondingly common case of determination by chance coincidence. She had pains of this kind while she was in an agitated state nursing her sick brother; and, owing to her exhaustion, she felt them more acutely than usual. These pains, which were originally associated only accidentally with those experiences, were later repeated in her memory as the somatic symbol of the whole complex of associations. I shall be able below to give several more examples in confirmation of this process. It seems probable that in the first instance these pains were rheumatic; that is to say, to give a definite sense to that much misused term, they were of a kind which resides principally in the muscles, involves a marked sensitiveness to pressure and modification of consistency in the muscles, is at its most severe after a considerable period of rest and immobilization of the extremity (i.e. in the morning), is improved by practising the painful movement and can be dissipated by massage. These myogenic pains, which are universally common, acquire great importance in neuropaths. They themselves regard them as nervous and are encouraged in this by their physicians, who are not in the habit of examining muscles by digital pressure. Such pains provide the material of countless neuralgias and so-called sciaticas, etc. I will only refer briefly here to the relation of these pains to the gouty diathesis. My patient's mother and two of her sisters suffered very severely from gout (or chronic rheumatism). Some part of the pains which she complained of at the time of the treatment may, like her original pains, have been of contemporary origin. I cannot tell, since I had no experience then in forming a judgement of this state of the muscles.

Evening. - She was in very good spirits and showed a great sense of humour. She told me incidentally that the affair of the lift was not as she had reported it. The proprietor had only said what he did in order to give an excuse for the lift not being used for downward journeys. She asked me a great many questions which had nothing pathological about them. She has had distressingly severe pains in her face, in her hand on the thumb side and in her leg. She gets stiff and has pains in her face if she sits without moving or stares at some fixed point for any considerable time. If she lifts anything heavy it brings on pains in her arm. - An examination of her right leg showed fairly good sensibility in her thigh, a high degree of anaesthesia in the lower part of the leg and in the foot and less in the region of the buttock and hip.

In hypnosis she informed me that she still occasionally has frightening ideas, such as that something might happen to her children, that they might fall ill or lose their lives, or that her brother, who is now on his honeymoon, might have an accident, or his wife might die (because the marriages of all her brothers and sisters had been so short). I could not extract any other fears from her. I forbade her any need to be frightened when there was no reason for it. She promised to give it up 'because you ask me to'. I gave her further suggestions for her pains, her leg, etc.

May 16. - She had slept well. She still complained of pains in her face, arms and legs. She was very cheerful. Her hypnosis yielded nothing. I applied a faradic brush to her anaesthetic leg.

Evening. - She gave a start as soon as I came in. 'I'm so glad you've come,' she said, 'I am so frightened.' At the same time she gave every indication of terror, together with stammering and *tic*. I first got her to tell me in her waking state what had happened. Crooking her fingers and stretching out her hands before her, she gave a vivid picture of her terror as she said: 'An enormous mouse suddenly whisked across my hand in the garden and was gone in a flash; things kept on gliding back wards and forwards.' (An illusion from the play of shadows?) 'A whole lot of mice were sitting in the trees. - Don't you hear the horses stamping in the circus? - There's a man groaning in the next room; he must be in pain after his operation. - Can I be in Rügen? Did I have a stove there like that?' She was confused by the multitude of thoughts crossing one another in her mind and by her efforts to sort out her actual surroundings from them. When I put questions to her about contemporary things, such as whether her daughters were here, she could make no answer.

I tried to disentangle the confusion of her mind under hypnosis. I asked her what it was that frightened her. She repeated the story of the mouse with every sign of terror, and added that as she went down the steps she saw a dreadful animal lying there, which vanished at once. I said that these were hallucinations and told her not to be frightened of mice; it was only drunkards who saw them (she disliked drunkards intensely). I told her the story of Bishop Hatto. She knew it too, and listened to it with extreme horror. - 'How did you come to think of the circus?' I went on to ask. She said that she had clearly heard the horses stamping in their stables near-by and getting tied up in their halters, which might injure them. When this happened Johann used to go out and untie them. I denied that there were stables near-by or that anyone in the next room had groaned. Did she know where she was? She said she knew now, but had thought earlier that she was in Rügen. I asked her how she got on to this memory. They had been talking in the garden, she said, of how hot it was in one part of it, and all at once the thought had come to her of the shadeless terrace in Rügen. Well then, I asked, what were her unhappy memories of her stay in Rügen? She produced a series of them. She had had the most frightful pains there in her legs and arms; when she was out on excursions there she had several times been caught in a fog and lost her way; twice, while she was on a walk, a bull had come after her, and so on. How was it that she had had this attack to-day? - How (she answered)? She had written a great many letters; it had taken her three hours and had given her a bad head. - I could assume, accordingly, that her attack of delirium was brought on by fatigue and that its content was determined by associations from such things as the shadeless place in the garden, etc. I repeated all the lessons I have been in the habit of giving her and left her composed to sleep.

May 17. - She had a very good night. In the bran bath which she had to-day, she gave some screams because she took the bran for worms. I heard this from the nurse. She herself was reluctant to tell me about it. She was almost exaggeratedly cheerful, but she kept interrupting herself with cries of 'ugh!' and made faces expressive of terror. She also stammered more than she has for the last few days. She told me she had dreamt last night that she was walking on a lot of leeches. The night before she had had horrible dreams. She had had to lay out a number of dead people and put them in coffins, but would not put the lids on. (Obviously, a recollection of her husband.) She told me further that in the course of her life she had had a large number of adventures with animals. The worst had been with a bat which had got caught in her wardrobe, so that she had rushed out of the room without any clothes on. To cure her of this fear her brother had given her a lovely brooch in the form of a bat; but she had never been able to wear it.

Under hypnosis she explained that her fear of worms came from her having once been given a present of a pretty pin cushion; but next morning, when she wanted to use it, a lot of little worms had crept out of it, because it had been filled with bran which was not quite dry. (A hallucination? Perhaps a fact.) I asked her to tell me some more animal stories. Once, she said, when she had been walking with her husband in a park in St. Petersburg, the whole path leading to a pond had been covered with toads, so that they had had to turn back. There had been times when she had been unable to hold out her hand to anyone, for fear of its turning into a dreadful animal, as had so often happened. I tried to free her from her fear of animals by going through them one by one and asking her if she was afraid of them. In the case of some of them she answered 'no'; in the case of others, 'I mustn't be afraid of them.'¹ I asked her why she had stammered and jerked about so much yesterday. She replied that she always did this when she was very frightened.² - But why *had* she been so frightened yesterday? - Because all kinds of oppressive thoughts had come into her head in the garden: in particular, how she could prevent something from heaping up again inside her after her treatment had come to an end. I repeated the three reasons for feeling reassured which I had already given her: (1) that she had become altogether healthier and more capable of resistance, (2) that she would get the habit of telling her thoughts to someone she was on close terms with, and (3) she would henceforth regard as indifferent a whole number of things which had hitherto weighed upon her. She went on to say that she had been worried as well because she had not thanked me for my visiting her late in the day; and she was afraid that I would lose patience with her on account of her recent relapse. She had been very much upset and alarmed because the house physician had asked a gentleman in the garden whether he was now able to face his operation. His wife had been sitting beside him, and she (the patient) could not help thinking that this might be the poor man's last evening. - After this last piece of information her depression seemed to be cleared up.³

Evening. - She was very cheerful and contented. The hypnosis produced nothing whatever. I devoted myself to dealing with her muscular pains and to restoring sensibility in her right leg. This was very easily accomplished in hypnosis, but her restored sensibility was in part lost again when she woke up. Before I left her she expressed her astonishment that it was such a long time since she had had any neck-cramps, though they usually came on before every thunderstorm.

¹ The procedure I was following here can scarcely be regarded as a good one: none of it was carried out exhaustively enough.

² Her stammering and clacking were not completely relieved after they had been traced back to the two initial traumas, though from then on the two symptoms were strikingly improved. The patient herself explained the incompleteness of the success as follows. She had got into the habit of stammering and clacking whenever she was frightened, so that in the end these symptoms had come to be attached not solely to the initial traumas but to a long chain of memories associated with them, which I had omitted to wipe out. This is a state of things which arises quite often and which always limits the beauty and completeness of the therapeutic outcome of the cathartic procedure.

³ It was here that I learnt for the first time, what was confirmed on countless later occasions, that when one is resolving a current hysterical delirium, the patient's communications are given in a reverse chronological order, beginning with the most recent and least important impressions and connections of thought and only at the end reaching the primary impression, which is in all probability the most important one causally.

May 18. - She had slept last night better than she had for years. But after her bath she complained of cold at the back of her neck, tightness and pains in the face, hands and feet. Her features were strained and her hands clenched. The hypnosis brought out no psychical content underlying her neck-cramp. I improved it by massage after she had woken up.¹

¹ Her astonishment the evening before at its being so long since she had had a neck-cramp was thus a premonition of an approaching condition which was already in preparation at the time and was perceived in the unconscious. This curious kind of premonition occurred regularly in the case already mentioned of Frau Cécilie M. If, for instance, while she was in the best of health, she said to me, 'It's a long time since I've been frightened of witches at night', or, 'how glad I am that I've not had pains in my eyes for such a long time', I could feel sure that the following night a severe onset of her fear of witches would be making extra work for her nurse or that her next attack of pains in the eyes was on the point of beginning. On each occasion what was already present as a finished product in the unconscious was beginning to show through indistinctly. This idea, which emerged as a sudden notion, was worked over by the unsuspecting 'official' consciousness (to use Charcot's term) into a feeling of satisfaction, which swiftly and invariably turned out to be unjustified. Frau Cécilie, who was a highly intelligent woman, to whom I am indebted for much help in gaining an understanding of hysterical symptoms, herself pointed out to me that events of this kind may have given rise to superstitions about the danger of being boastful or of anticipating evils. We must not vaunt our happiness on the one hand, nor, on the other, must we talk of the worst or it will happen. The fact is that we do not boast of our happiness until unhappiness is in the offing, and we become aware of our anticipation in the form of a boast, because in such cases the subject-matter of what we are recollecting emerges before the feeling that belongs to it - that is to say, because an agreeable contrasting idea is present in consciousness.

I hope that this extract from the history of the first three weeks of the treatment will be enough to give a clear picture of the patient's state, of the character of my therapeutic efforts and of the measure of their success. I shall now proceed to amplify the case history.

The delirium which I have last described was also the last considerable disturbance in Frau Emmy von N.'s condition. Since I did not take the initiative in looking for the symptoms and their basis, but waited for something to come up in the patient or for her to tell me some thought that was causing her anxiety, her hypnoses soon ceased to produce material. I therefore made use of them principally for the purpose of giving her maxims which were to remain constantly present in her mind and to protect her from relapsing into similar conditions when she had got home. At that time I was completely under the sway of Bernheim's book on suggestion and I anticipated more results from such didactic measures than I should to-day. My patient's condition improved so rapidly, that she soon assured me she had not felt so well since her husband's death. After a treatment lasting in all for seven weeks I allowed her to return to her home on the Baltic.

It was not I but Dr. Breuer who received news of her about seven months later. Her health had continued good for several months but had then broken down again as a result of a fresh psychological shock. Her elder daughter, during their first stay in Vienna, had already followed her mother in developing neck-cramps and mild hysterical states; but in particular, she had suffered from pains in walking owing to a retroverted uterus. On my advice she had gone for treatment to Dr. N., one of our most distinguished gynaecologists, who had put her uterus right by massage, and she had remained free from trouble for several months. Her trouble recurred, however, while they were at home, and her mother called in a gynaecologist from the neighbouring University town. He prescribed a combined local and general treatment for the girl, which, however, brought on a severe nervous illness (she was seventeen at the time). It is probable that this was already an indication of her pathological disposition which was to manifest itself a year later in a character-change. Her mother, who had handed the girl over to the doctors with her usual mixture of docility and mistrust, was overcome by the most violent self-reproaches after the unfortunate outcome of the treatment. A train of thought which I have not investigated brought her to the conclusion that Dr. N. and I were together responsible for the girl's illness because we had made light of her serious condition. By an act of will as it were, she undid the effects of my treatment and promptly, relapsed into the states from which I had freed her. A distinguished physician in her neighbourhood, to whom she went for advice, and Dr. Breuer, who was in correspondence with her, succeeded in convincing her of the innocence of the two targets of her accusations; but even after this was cleared up, the aversion to me which she formed at the time was left over as a hysterical residue, and she declared that it was impossible for her to take up her treatment with me again. On the advice of the same medical authority she turned for help to a Sanatorium in North Germany. At Breuer's desire I explained to the physician in charge the modifications of hypnotic therapy which I had found effective in her case.

This attempted transfer failed completely. From the very first she seems to have been at cross-purposes with the doctor. She exhausted herself in resisting whatever was done for her. She went downhill, lost sleep and appetite, and only recovered after a woman friend of hers who visited her in the Sanatorium in effect secretly abducted her and looked after her in her house. A short time afterwards, exactly a year after her first meeting with me, she was again in Vienna and put herself once more into my hands.

I found her much better than I had expected from the accounts I had received by letter. She could get about and was free from anxiety; much of what I had accomplished the year before was still maintained. Her chief complaint was of frequent states of confusion - 'storms in her head' as she called them. Besides this she suffered from sleeplessness, and was often in tears for hours at a time. She felt sad at one particular time of day (five o'clock). This was the regular hour at which, during the winter, she had been able to visit her daughter in the nursing home. She stammered and clacked a great deal and kept rubbing her hands together as though she was in a rage, and when I asked her if she saw a great many animals, she only replied: 'Oh keep still!'

At my first attempt to induce hypnosis she clenched her fists and exclaimed: 'I won't be given any antipyrin injections; I would rather have my pains! I don't like Dr. R.; he is antipathetic to me.' I perceived that she was involved in the memory of being hypnotized in the sanatorium, and she calmed down as soon as I brought her back to the present situation.

At the very beginning of the treatment I had an instructive experience. I had asked her how long she had had a recurrence of the stammering, and she had hesitatingly answered (under hypnosis) that it was ever since a shock she had at D--- during the winter. A waiter at the hotel in which she was staying had concealed himself in her bedroom. In the darkness, she said, she had taken the object for an overcoat and put out her hand to take hold of it; and the man had suddenly 'shot up into the air'. I took this memory-picture away, and in fact from that time on she ceased to stammer noticeably either in hypnosis or in waking life. I cannot remember what it was that led me to test the success of my suggestion, but when I returned the same evening I asked her in an apparently innocent voice how I could manage to fasten the door when I went away (while she was lying asleep) so that no one could slip into the room. To my astonishment she gave a violent start and began grinding her teeth and rubbing her hands. She indicated that she had had a severe shock of that kind at D---, but could not be persuaded to tell me the story. I observed that she had in mind the same story which she had told me that morning during the hypnosis and which I thought I had wiped out. In her next hypnosis she told me the story in greater detail and more truthfully. In her excitement she had been walking up and down the passage and found the door of her maid's bed room open. She had tried to go in and sit down. Her maid had stood in the way, but she refused to be stopped and walked in, and then caught sight of the dark object against the wall which turned out to be a man. It was evidently the erotic factor in this little adventure which had caused her to give an untrue account of it. This taught me that an incomplete story under hypnosis produces no therapeutic effect. I accustomed myself to regarding as incomplete any story that brought about no improvement, and I gradually came to be able to read from patients' faces whether they might not be concealing an essential part of their confessions.

The work that I had to do with her this time consisted in dealing in hypnosis with the disagreeable impressions she had received during her daughter's treatment and during her own stay in the sanatorium. She was full of suppressed anger with the physician who had compelled her under hypnosis to spell out the word 't . . . o . . . a . . . d' and she made me promise never to make her say it. In this connection I ventured upon a practical joke in one of my suggestions to her. This was the only abuse of hypnosis - and a fairly innocent one at that - of which I have to plead guilty with this patient. I assured her that her stay in the sanatorium at '-*tal* [-'vale'] would become so remote to her that she would not even be able to recall its name and that whenever she wanted to refer to it she would hesitate between '-*berg* [-'hill'], '-*tal*', '-*wald* [-'wood'] and so on. This duly happened and presently the only remaining sign of her speech-inhibition was her uncertainty over this name. Eventually, following a remark by Dr. Breuer, I relieved her of this compulsive paramnesia.

I had a longer struggle with what she described as 'the storms in her head' than with the residues of these experiences. When I first saw her in one of these states she was lying on the sofa with her features distorted and her whole body unceasingly restless. She kept on pressing her hands to her forehead and calling out in yearning and helpless tones the name 'Emmy', which was her elder daughter's as well as her own. Under hypnosis she informed me that this state was a repetition of the many fits of despair by which she had been overcome during her daughter's treatment, when, after she had spent hours in trying to discover some means of correcting its bad effects, no way out presented itself. When, at such a time, she felt her thoughts becoming confused, she made it a practice to call out her daughter's name, so that it might help her back to clear-headedness. For, during the period when her daughter's illness was imposing fresh duties on her and she felt that her own nervous condition was once again gaining strength over her, she had determined that whatever had to do with the girl must be kept free from confusion, however chaotic everything else in her head was.

In the course of a few weeks we were able to dispose of these memories too and Frau Emmy remained under my observation for some time longer, feeling perfectly well. At the very end of her stay something happened which I shall describe in detail, since it throws the strongest light on the patient's character and the manner in which her states came about.

I called on her one day at lunch-time and surprised her in the act of throwing something wrapped up in paper into the garden, where it was caught by the children of the house-porter. In reply to my question, she admitted that it was her (dry) pudding, and that this went the same way every day. This led me to investigate what remained of the other courses and I found that there was more than half left on the plates. When I asked her why she ate so little she answered that she was not in the habit of eating more and that it would be bad for her if she did; she had the same constitution as her late father, who had also been a small eater. When I enquired what she drank she told me she could only tolerate thick fluids, such as milk, coffee or cocoa; if she ever drank water or minerals it ruined her digestion. This bore all the signs of a neurotic choice. I took a specimen of her urine and found it was highly concentrated and overcharged with urates.

I therefore thought it advisable to recommend her to drink more and decided also to increase the amount of her food. It is true that she did not look at all noticeably thin but I nevertheless thought it worth while to aim at feeding her up a little. When on my next visit I ordered her some alkaline water and forbade her usual way of dealing with her pudding, she showed considerable agitation. 'I'll do it because you ask me to,' she said, 'but I can tell you in advance that it will turn out badly, because it is contrary to my nature, and it was the same with my father.' When I asked her under hypnosis why it was that she could not eat more or drink any water, she answered in a rather sullen tone: 'I don't know.' Next day the nurse reported that she had eaten the whole of her helpings and had drunk a glass of the alkaline water. But I found Frau Emmy herself lying in a profoundly depressed state and in a very ungracious mood. She complained of having very violent gastric pains. 'I told you what would happen,' she said. 'We have sacrificed all the successful results that we have been struggling for so long. I've ruined my digestion, as always happens if I eat more or drink water, and I have to starve myself entirely for five days to a week before I can tolerate anything.' I assured her that there was no need to starve herself and that it was impossible to ruin one's digestion in that way: her pains were only due to the anxiety over eating and drinking. It was clear that this explanation of mine made not the slightest impression on her. For when, soon afterwards, I tried to put her to sleep, for the first time I failed to bring about hypnosis; and the furious look she cast at me convinced me that she was in open rebellion and that the situation was very grave. I gave up trying to hypnotize her, and announced that I would give her twenty-four hours to think things over and accept the view that her gastric pains came only from her fear. At the end of this time I would ask her whether she was still of the opinion that her digestion could be ruined for a week by drinking a glass of mineral water and eating a modest meal; if she said yes, I would ask her to leave. This little scene was in very sharp contrast to our normal relations, which were most friendly.

I found her twenty-four hours later, docile and submissive. When I asked her what she thought about the origin of her gastric pains, she answered, for she was incapable of prevarication: 'I think they come from my anxiety, but only because you say so.' I then put her under hypnosis and asked her once again: 'Why can't you eat more?'

The answer came promptly and consisted once more in her producing a series of chronologically arranged reasons from her store of recollections: 'I'm thinking how, when I was a child, it often happened that out of naughtiness I refused to eat my meat at dinner. My mother was very severe about this and under the threat of condign punishment I was obliged two hours later to eat the meat, which had been left standing on the same plate. The meat was quite cold by then and the fat was set so hard' (she showed her disgust) '... I can still see the fork in front of me ... one of its prongs was a little bent. Whenever I sit down to a meal I see the plates before me with the cold meat and fat on them. And how, many years later, I lived with my brother who was an officer and who had that horrible disease. I knew it was contagious and was terribly afraid of making a mistake and picking up his knife and fork' (she shuddered) '... and in spite of that I ate my meals with him so that no one should know that he was ill. And how, soon after that, I nursed my other brother when he had consumption so badly. We sat by the side of his bed and the spittoon always stood on the table, open' (she shuddered again) '... and he had a habit of spitting across the plates into the spittoon. This always made me feel so sick, but I couldn't show it, for fear of hurting his feelings. And these spittoons are still on the table whenever I have a meal and they still make me feel sick.' I naturally made a thorough clearance of this whole array of agencies of disgust and then asked why it was that she could not drink water. When she was seventeen, she replied, the family had spent some months in Munich and almost all of them had contracted gastric catarrh owing to the bad drinking water. In the case of the others the trouble was quickly relieved by medical attention, but with her it had persisted. Nor had she been improved by the mineral water which she was recommended. When the doctor had prescribed it she had thought at once 'that won't be any use'. From that time onwards this intolerance both of ordinary water and mineral water had recurred on countless occasions.

The therapeutic effect of these discoveries under hypnosis was immediate and lasting. She did not starve herself for a week but the very next day she ate and drank without making any difficulty. Two months later she wrote in a letter: 'I am eating excellently and have put on a great deal of weight. I have already drunk forty bottles of the water. Do you think I should go on with it?'

I saw Frau von N. again in the spring of the following year at her estate near D---. At this time her elder daughter, whose name she had called out during her 'storms in the head', entered on a phase of abnormal development. She exhibited unbridled ambitions which were out of all proportion to the poverty of her gifts, and she became disobedient and even violent towards her mother. I still enjoyed her mother's confidence and was sent for to give my opinion on the girl's condition. I formed an unfavourable impression of the psychological change that had occurred in the girl, and in arriving at a prognosis I had also to take into account the fact that all her step-brothers and sisters (the children of Herr von N. by his first marriage) had succumbed to paranoia. In her mother's family, too, there was no lack of a neuropathic heredity, although none of her more immediate relatives had developed a chronic psychosis. I communicated to Frau von N. without any reservation the opinion for which she had asked and she received it calmly and with understanding. She had grown stout, and looked in flourishing health. She had felt relatively very well during the nine months that had passed since the end of her last treatment. She had only been disturbed by slight neck-cramps and other minor ailments. During the several days which I spent in her house I came for the first time to realize the whole extent of her duties, occupations and intellectual interests. I also met the family doctor, who had not many complaints to make about the lady; so she had to some degree come to terms with the profession.

She was thus in very many respects healthier and more capable, but in spite of all my improving suggestions there had been little change in her fundamental character. She seemed not to have accepted the existence of a category of 'indifferent things'. Her inclination to torment herself was scarcely less than it had been at the time of her treatment. Nor had her hysterical disposition been quiescent during this good period. She complained, for instance, of an inability to make journeys of any length by train. This had come on during the last few months. A necessarily hurried attempt to relieve her of this difficulty resulted only in her producing a number of trivial disagreeable impressions left by some recent journeys she had made to D--- and its neighbourhood. She seemed reluctant, however, to be communicative under hypnosis, and even then I began to suspect that she was on the point of withdrawing once more from my influence and that the secret purpose of her railway inhibition was to prevent her making a fresh journey to Vienna.

It was during these days, too, that she made her complaints about gaps in her memory 'especially about the most important events', from which I concluded that the work I had done two years previously had been thoroughly effective and lasting. - One day, she was walking with me along an avenue that led from the house to an inlet in the sea and I ventured to ask whether the path was often infested by toads. By way of reply she threw a reproachful glance at me, though unaccompanied by signs of horror; she amplified this a moment later with the words 'but the ones here are *real*'. During the hypnosis, which I induced in order to deal with her railway inhibition, she herself seemed dissatisfied with the answers she gave me, and she expressed a fear that in future she was likely to be less obedient under hypnosis than before. I determined to convince her of the contrary. I wrote a few words on a piece of paper, handed it to her and said: 'At lunch to-day you will pour me out a glass of red wine, just as you did yesterday. As I raise the glass to my lips you will say: "Oh, please pour me out a glass, too", and when I reach for the bottle, you will say: "No thank you, I don't think I will after all". You will then put your hand in your bag, draw out the piece of paper and find those same words written on it.' This was in the morning. A few hours later the little episode took place exactly as I had pre-arranged it, and so naturally that none of the many people present noticed anything. When she asked me for the wine she showed visible signs of an internal struggle - for she never drank wine - and after she had refused the drink with obvious relief, she put her hand into her bag and drew out the piece of paper on which appeared the last words she had spoken. She shook her head and stared at me in astonishment.

After my visit in May, 1890, my news of Frau von N. became gradually scantier. I heard indirectly that her daughter's deplorable condition, which caused her every kind of distress and agitation, did eventually undermine her health. Finally, in the summer of 1893, I had a short note from her asking my permission for her to be hypnotized by another doctor, since she was ill again and could not come to Vienna. At first I did not understand why my permission was necessary, till I remembered that in 1890 I had, at her own request, protected her against being hypnotized by anyone else, so that there should be no danger of her being distressed by coming under the control of a doctor who was antipathetic to her, as had happened at *-berg (-tal, -wald)*. I accordingly renounced my exclusive prerogative in writing.

DISCUSSION

Unless we have first come to a complete agreement upon the terminology involved, it is not easy to decide whether a particular case is to be reckoned as a hysteria or some other neurosis (I am speaking here of neuroses which are not of a purely neurasthenic type; and we have still to await the directing hand which shall set up boundary-marks in the region of the commonly occurring mixed neuroses and which shall bring out the features essential for their characterization. If, accordingly, we are still accustomed to diagnosing a hysteria, in the narrower sense of the term, from its similarity to familiar typical cases, we shall scarcely be able to dispute the fact that the case of Frau Emmy von N. was one of hysteria. The mildness of her deliria and hallucinations (while her other mental activities remained intact), the change in her personality and store of memories when she was in a state of artificial somnambulism, the anaesthesia in her painful leg, certain data revealed in her anamnesis, her ovarian neuralgia, etc., admit of no doubt as to the hysterical nature of the illness, or at least of the patient. That the question can be raised at all is due only to one particular feature of the case, which also provides an opportunity for a comment that is of general validity. As we have explained in the 'Preliminary Communication' which appears at the beginning of this volume, we regard hysterical symptoms as the effects and residues of excitations which have acted upon the nervous system as traumas. Residues of this kind are not left behind if the original excitation has been discharged by abreaction or thought-activity. It is impossible any longer at this point to avoid introducing the idea of quantities (even though not measurable ones). We must regard the process as though a sum of excitation impinging on the nervous system is transformed into chronic symptoms in so far as it has not been employed for external action in proportion to its amount. Now we are accustomed to find in hysteria that a considerable part of this 'sum of excitation' of the trauma is transformed into purely somatic symptoms. It is this characteristic of hysteria which has so long stood in the way of its being recognized as a psychical disorder.

If, for the sake of brevity, we adopt the term 'conversion' to signify the transformation of psychical excitation into chronic somatic symptoms, which is so characteristic of hysteria, then we may say that the case of Frau Emmy von N. exhibited only a small amount of conversion. The excitation, which was originally psychical, remained for the most part in the psychical sphere, and it is easy to see that this gives it a resemblance to the other, non-hysterical neuroses. There are cases of hysteria in which the whole surplus of stimulation undergoes conversion, so that the somatic symptoms of hysteria intrude into what appears to be an entirely normal consciousness. An incomplete transformation is however more usual, so that some part at least of the affect that accompanies the trauma persists in consciousness as a component of the subject's state of feeling.

The psychical symptoms in our present case of hysteria with very little conversion can be divided into alterations of mood (anxiety, melancholic depression), phobias and abulias (inhibitions of will). The two latter classes of psychical disturbance are regarded by the French school of psychiatrists as stigmata of neurotic degeneracy, but in our case they are seen to have been adequately determined by traumatic experiences. These phobias and abulias were for the most part of traumatic origin, as I shall show in detail.

Some of the phobias, it is true, corresponded to the primary phobias of human beings, and especially of neuropaths - in particular, for instance, her fear of animals (snakes and toads, as well as all the vermin of which Mephistopheles boasted himself master), and of thunderstorms and so on. But these phobias too were established more firmly by traumatic events. Thus her fear of toads was strengthened by her experience in early childhood of having a dead toad thrown at her by one of her brothers, which led to her first attack of hysterical spasms; and similarly, her fear of thunderstorms was brought out by the shock which gave rise to her clacking, and her fear of fogs by her walk on the Island of Rügen. Nevertheless, in this group the primary - or, one might say, the instinctive - fear (regarded as a psychical stigma) plays the preponderant part.

The other, more specific phobias were also accounted for by particular events. Her dread of unexpected and sudden shocks was the consequence of the terrible impression made on her by seeing her husband, when he seemed to be in the best of health, succumb to a heart-attack before her eyes. Her dread of strangers, and of people in general, turned out to be derived from the time when she was being persecuted by her family and was inclined to see one of their agents in every stranger and when it seemed to her likely that strangers knew of the things that were being spread abroad about her in writing and by word of mouth. Her fear of asylums and their inmates went back to a whole series of unhappy events in her family and to stories poured into her listening ears by a stupid servant-girl. Apart from this, this phobia was supported on the one hand by the primary and instinctive horror of insanity felt by healthy people, and on the other hand by the fear, felt by her no less than by all neurotics, of going mad herself. Her highly specific fear that someone was standing behind her was determined by a number of terrifying experiences in her youth and later life. Since the episode in the hotel, which was especially distressing to her because of its erotic implications, her fear of a stranger creeping into her room was greatly emphasized. Finally, her fear of being buried alive, which she shared with so many neuropaths, was entirely explained by her belief that her husband was not dead when his body was carried out - a belief which gave such moving expression to her inability to accept the fact that her life with the man she loved had come to a sudden end. In my opinion, however, all these psychical factors, though they may account for the *choice* of these phobias, cannot explain their *persistence*. It is necessary, I think, to adduce a *neurotic* factor to account for this persistence - the fact that the patient had been living for years in a state of sexual abstinence. Such circumstances are among the most frequent causes of a tendency to anxiety.

Our patient's abulias (inhibitions of will, inability to act) admit even less than the phobias of being regarded as psychical stigmata due to a general limitation of capacity. On the contrary, the hypnotic analysis of the case made it clear that her abulias were determined by a twofold psychical mechanism which was at bottom a single one. In the first place an abulia may simply be the consequence of a phobia. This is so when the phobia is attached to an action of the subject's own instead of to an expectation - for instance, in our present case, the fear of going out or of mixing with people, as compared with the fear of someone creeping into the room. Here the inhibition of will is caused by the anxiety attendant upon the performance of the action. It would be wrong to regard abulias of this kind as symptoms distinct from the corresponding phobias, though it must be admitted that such phobias can exist (provided they are not too severe) without producing abulias. The second class of abulias depends on the presence of affectively-toned and unresolved associations which are opposed to linking up with other associations, and particularly with any that are incompatible with them. Our patient's anorexia offers a most brilliant instance of this kind of abulia. She ate so little because she did not like the taste, and she could not enjoy the taste because the act of eating had from the earliest times been connected with memories of disgust whose sum of affect had never been to any degree diminished; and it is impossible to eat with disgust and pleasure at the same time. Her old-established disgust at meal times had persisted undiminished because she was obliged constantly to suppress it, instead of getting rid of it by reaction. In her childhood she had been forced, under threat of punishment, to eat the cold meal that disgusted her, and in her later years she had been prevented out of consideration for her brothers from expressing the affects to which she was exposed during their meals together.

At this point I may perhaps refer to a short paper in which I have tried to give a psychological explanation of hysterical paralyses (Freud 1893c). I there arrived at a hypothesis that the cause of these paralyses lay in the inaccessibility to fresh associations of a group of ideas connected, let us say, with one of the extremities of the body; this associative inaccessibility depended in turn on the fact that the idea of the paralysed limb was involved in the recollection of the trauma - a recollection loaded with affect that had not been disposed of. I showed from examples from ordinary life that a cathexis such as this of an idea whose affect is unresolved always involves a certain amount of associative inaccessibility and of incompatibility with new cathexes.

I have not hitherto succeeded in confirming, by means of hypnotic analysis, this theory about motor paralyses, but I can adduce Frau von N.'s anorexia as proving that this mechanism is the operative one in certain abulias, and abulias are no thing other than a highly specialized - or, to use a French expression, 'systematized' - kind of psychical paralysis.

Frau von N.'s psychical situation can be characterized in all essentials by emphasizing two points. (1) The distressing affects attaching to her traumatic experiences had remained unresolved - for instance, her depression, her pain (about her husband's death), her resentment (at being persecuted by his relatives), her disgust (at the compulsory meals), her fear (about her many frightening experiences), and so on. (2) Her memory exhibited a lively activity which, sometimes spontaneously, sometimes in response to a contemporary stimulus (e.g. the news of the revolution in San Domingo), brought her traumas with their accompanying affects bit by bit into her present-day consciousness. My therapeutic procedure was based on the course of this activity of her memory and endeavoured day by day to resolve and get rid of whatever that particular day had brought to the surface, till the accessible stock of her pathological memories seemed to be exhausted.

These two psychical characteristics, which I regard as generally present in hysterical paroxysms, opened the way to a number of important considerations. I will, however, put off discussing them till I have given some attention to the mechanism of the somatic symptoms.

It is not possible to assign the same origin to all the somatic symptoms of these patients. On the contrary, even from this case, which was not rich in them, we find that the somatic symptoms of a hysteria can arise in a variety of ways. I will venture, in the first place, to include pains among somatic symptoms. So far as I can see, one set of Frau von N.'s pains were certainly determined organically by the slight mortifications (of a rheumatic kind) in the muscles, tendons or fascia which cause so much more pain to neurotics than to normal people. Another set of pains were in all probability *memories* of pains - were mnemonic symbols of the times of agitation and sick-nursing which played such a large part in the patient's life. These pains, too, may well have been originally justified on organic grounds but had since then been adapted for the purposes of the neurosis. I base these assertions about Frau von N.'s pains mainly on observations made elsewhere which I shall report on a later page. On this particular point little information could be gathered from the patient herself.

Some of the striking motor phenomena exhibited by Frau von N. were simply an expression of the emotions and could easily be recognized in that light. Thus, the way in which she stretched her hands in front of her with her fingers spread out and crooked expressed horror, and similarly her facial play. This, of course, was a more lively and uninhibited way of expressing her emotions than was usual with women of her education and race. Indeed, she herself was restrained, almost stiff in her expressive movements when she was not in a hysterical state. Others of her motor symptoms were, according to herself, directly related to her pains. She played restlessly with her fingers (1888) or rubbed her hands against one another (1889) so as to prevent herself from screaming. This reason reminds one forcibly of one of the principles laid down by Darwin to explain the expression of the emotions - the principle of the overflow of excitation, which accounts, for instance, for dogs wagging their tails. We are all of us accustomed, when we are affected by painful stimuli, to replace screaming by other sorts of motor innervations. A person who has made up his mind at the dentist's to keep his head and mouth still and not to put his hand in the way, may at least start drumming with his feet.

A more complicated method of conversion is revealed by Frau von N.'s *tic*-like movements, such as clicking with the tongue and stammering, calling out the name 'Emmy' in confusional states, using the composite formula 'Keep still! Don't say anything! Don't touch me!' (1888). Of these motor manifestations, the stammering and clacking can be explained in accordance with a mechanism which I have described, in a short paper on the treatment of a case by hypnotic suggestion (1892-93), as 'the putting into effect of antithetic ideas'. The process, as exemplified in our present instance, would be as follows. Our hysterical patient, exhausted by worry and long hours of watching by the bedside of her sick child which had at last fallen asleep, said to herself: 'Now you must be perfectly still so as not to awaken the child.' This intention probably gave rise to an antithetic idea in the form of a fear that she might make a noise all the same that would wake the child from the sleep which she had so long hoped for. Similar antithetic ideas arise in us in a marked manner when we feel uncertain whether we can carry out some important intention.

Neurotics, in whose self-feeling we seldom fail to find a strain of depression or anxious expectation, form greater numbers of these antithetic ideas than normal people, or perceive them more easily; and they regard them as of more importance. In our patient's state of exhaustion the antithetic idea, which was normally rejected, proved itself the stronger. It is this idea which put itself into effect and which, to the patient's horror, actually produced the noise she dreaded. In order to explain the whole process it may further be assumed that her exhaustion was only a partial one; it affected, to use the terminology of Janet and his followers, only her 'primary ego' and did not result in a weakening of the antithetic idea as well.

It may further be assumed that it was her horror at the noise produced against her will that made the moment a traumatic one, and fixed the noise itself as a somatic mnemonic symptom of the whole scene. I believe, indeed, that the character of the *tic* itself, consisting as it did of a succession of sounds which were convulsively emitted and separated by pauses and which could be best likened to clackings, reveals traces of the process to which it owed its origin. It appears that a conflict had occurred between her intention and the antithetic idea (the counter-will) and that this gave the *tic* its discontinuous character and confined the antithetic idea to paths other than the habitual ones for innervating the muscular apparatus of speech.

The patient's spastic inhibition of speech, her peculiar stammer, was the residue of an essentially similar exciting cause. Here, however, it was not the *outcome* of the final innervation - the exclamation - but the process of innervation itself - the attempted convulsive inhibition of the organs of speech - which was made into a symbol of the event for her memory.

These two symptoms, the clacking and the stammering, which were thus closely related through the history of their origin, continued to be associated and were turned into chronic symptoms after being repeated on a similar occasion. Thereafter they were put to a further use. Having originated at a moment of violent fright, they were thenceforward joined to any fright (in accordance with the mechanism of monosymptomatic hysteria which will be described in Case 5), even when the fright could not lead to an antithetic idea being put into effect.

The two symptoms were eventually linked up with so many traumas, had so much reason for being reproduced in memory, that they perpetually interrupted the patient's speech for no particular cause, in the manner of a meaningless *tic*. Hypnotic analysis, however, was able to demonstrate how much meaning lay concealed behind this apparent *tic*; and if the Breuer procedure did not succeed in this case in getting rid of the two symptoms completely at a single blow, that was because the catharsis had extended only to the three principal traumas and not to the secondarily associated ones.¹

¹ I may here be giving an impression of laying too much emphasis on the details of the symptoms and of becoming lost in an unnecessary maze of sign-reading. But I have come to learn that the determination of hysterical symptoms does in fact extend to their subtlest manifestations and that it is difficult to attribute too much sense to them. Let me give an example to justify this statement. Some months ago I had under my treatment an eighteen-year-old girl belonging to a family with a bad heredity. Hysteria played its full part in her complex neurosis. The first thing I heard from her was a complaint that she suffered from attacks of despair of two varieties. In one variety she felt drawing and pricking sensations in the lower part of her face, from her cheeks down towards her mouth; in the other variety the toes of both her feet were stretched out convulsively and kept on wriggling about. To begin with I myself was unwilling to attach much importance to these details, and there can be no doubt that earlier students of hysteria would have been inclined to regard these phenomena as evidence of the stimulation of cortical centres during a hysterical attack. It is true that we are ignorant of the locality of the centres for paraesthesias of this kind, but it is well known that such paraesthesias usher in partial epilepsy and constitute Charcot's sensory epilepsy. Symmetrical cortical areas in the immediate vicinity of the median fissure might be held responsible for the movement of the toes. But the explanation turned out to be a different one. When I had come to know the girl better I put a straight question to her as to what kind of thoughts came to her during these attacks. I told her not to be embarrassed and said that she must be able to give an explanation of the two phenomena. The patient turned red with shame, but I was able to persuade her in the end, without using hypnosis, to give the following account, the truth of which was fully confirmed by her companion, who was present at the time. From the time when her periods first set in she had suffered for years from *cephalagia adolescentium* which had made any regular occupation impossible and had interfered with her education. When at last she was freed from this disability, this ambitious and rather simple-minded child was determined to work extremely hard at her own improvement, so as to catch up once more with her sisters and contemporaries. In doing so she made quite unreasonable efforts, and an effort of this kind usually ended in an outburst of despair at having over-estimated her powers. She also, of course, compared herself with other girls physically and felt unhappy when she discovered some physical disadvantage in herself. Her teeth projected noticeably, and she began to feel upset about this. She got the idea of correcting the defect by practising for a quarter of an hour at a time pulling down her upper lip over the projecting teeth. The failure of these childish efforts once led to a fit of despair; and thenceforward the drawing and pricking sensations from the cheek downwards were established as the content of one of her two varieties of attack. The origin of the other variety - with its motor symptoms of stretching out and wriggling the toes - was no less easily found. I was told that her first attack of this kind followed after an excursion on the Schafberg near Ischl, and her relatives were naturally inclined to set it down to over-exertion. But the girl herself told me a different story. It seems that it was a favourite habit of the sisters to tease one another about the large size of their feet - an undeniable fact. The patient had long felt unhappy over this blemish and tried to force her feet into the tightest possible boots. Her observant father, however, would not allow this and saw to it that she only wore comfortable-fitting footwear. She was much dissatisfied with this regulation. She thought about it all the time and acquired the habit of wriggling her toes about in her shoes, as people do when they want to discover whether a shoe is much too large, how much smaller a size they could take, etc. During the excursion on the Schafberg (which she was far from finding an exertion) there was once again, of course, an opportunity for her attention to be drawn to the subject of shoes, in view of the shortened skirts she wore. One of her sisters said to her in the course of the walk: 'You've put extra big shoes on to-day.' She experimented by wriggling her toes and got the same impression. Thenceforward she could not escape from her agitation about the unlucky size of her feet, and when they got back from the walk her first attack came on; her toes curled up and moved about involuntarily as a mnemonic symbol of the whole depressing train of thought.

I may point out that what we are dealing with here are attacks and not chronic symptoms. I may also add that after the patient's confession her first variety of symptoms ceased, but the second variety - her attacks of wriggling her toes - persisted. There must therefore have been something left over, which she had not confessed.

Postscript. I learnt later that the reason why the foolish girl worked so hard at beautifying herself was that she wanted to attract a young cousin of hers. - [Added 1924:] Some years later her neurosis turned into a dementia praecox.

In accordance with the rules governing hysterical attacks, the exclamation of 'Emmy' during her attacks of confusion reproduced, it will be remembered, her frequent states of helplessness during her daughter's treatment. This exclamation was linked to the content of the attack by a complex train of thought and was in the nature of a protective formula against the attack. The exclamation would probably, through a more extended application of its meaning, have degenerated into a *tic*, as had in fact already happened in the case of the complicated protective formula 'Don't touch me', etc. In both these instances hypnotic treatment prevented any further development of the symptoms; but the exclamation 'Emmy' had only just come into existence, and I caught it while it was still on its native soil, restricted to attacks of confusion.

As we have seen, these motor symptoms originated in various ways: by putting an antithetic idea into effect (as in the clacking), by a simple conversion of psychical excitation into motor activity (as in the stammering), or by a voluntary action during a hysterical paroxysm (as in the protective measures exemplified by the exclamation 'Emmy' and the longer formula). But however these motor symptoms may have originated, they all have this one thing in common. They can be shown to have an original or long-standing connection with traumas, and stand as symbols for them in the activities of the memory.

Others of the patient's somatic symptoms were not of a hysterical nature at all. This is true, for example, of the neck-cramps, which I regard as a modified form of migraine and which as such are not to be classed as a neurosis but as an organic disorder. Hysterical symptoms, however, regularly become attached to these. Frau von N.'s neck-cramps, for instance, were employed for the purpose of hysterical attacks, whereas she did not have the typical symptomatology of hysterical attacks at her disposal.

I will amplify this description of Frau von N.'s psychical state by considering the pathological changes of consciousness which could be observed in her. Like her neck-cramps, distressing present-day events (cf. her last delirium in the garden) or anything which powerfully recalled any of her traumas brought her into a state of delirium. In such states - and the few observations I made led me to no other conclusion - there was a limitation of consciousness and a compulsion to associate similar to that prevailing in dreams; hallucinations and illusions were facilitated to the highest degree and feeble-minded or even nonsensical inferences were made. This state, which was comparable to one of hallucinatory alienation probably represented an attack. It might be regarded as an acute psychosis (serving as the equivalent of an attack) which would be classified as a condition of 'hallucinatory confusion'. A further resemblance between such states of hers and a typical hysterical attack was shown by the fact that a portion of the old-established traumatic memories could usually be detected underlying the delirium. The transition from a normal state to a delirium often occurred quite imperceptibly. She would be talking quite rationally at one moment about matters of small emotional importance, and as her conversation passed on to ideas of a distressing kind I would notice, from her exaggerated gestures or the appearance of her regular formulas of speech, etc., that she was in a state of delirium. At the beginning of the treatment the delirium lasted all day long; so that it was difficult to decide with certainty whether any given symptoms - like her gestures - formed part of her psychical state merely as symptoms of an attack, or whether - like the clacking and stammering - they had become genuine chronic symptoms. It was often only possible *after the event* to distinguish between what had happened in a delirium and what had happened in her normal state. For the two states were separated in her memory, and she would sometimes be highly astonished to hear of the things which the delirium had introduced piecemeal into her normal conversation. My very first interview with her was the most remarkable instance of the way in which the two states were interwoven without paying any attention to each other. Only at one moment of this psychical see-sawing did it happen that her normal consciousness, in touch with the present day, was affected. This was when she gave me an answer which originated from her delirium and said she was 'a woman dating from last century'.

The analysis of these states of delirium in Frau von N. was not exhaustively carried out. This was mainly because her condition improved so rapidly that the deliria became sharply differentiated from her normal life and were restricted to the periods of her neck-cramps. On the other hand, I gathered a great deal of information about the patient's behaviour in a third state, that of artificial somnambulism. Whereas in her normal state she had no knowledge of the psychical experiences during her deliria and during her somnambulism, she had access during somnambulism to the memories of all three states. In point of fact, therefore, she was at her most normal in the state of somnambulism. Indeed, if I leave on one side the fact that in somnambulism she was far less reserved with me than she was at her best moments in ordinary life - that is, that in somnambulism she gave me information about her family and such things, while at other times she treated me as a stranger - and if, further, I disregard the fact that she exhibited the full degree of suggestibility characteristic of somnambulism, I am bound to say that during her somnambulism she was in a completely normal state. It was interesting to notice that on the other hand her somnambulism showed no trace of being super-normal, but was subject to all the mental failings that we are accustomed to associate with a normal state of consciousness.

The examples which follow throw light on the behaviour of her memory in somnambulism. In conversation one day she expressed her delight at the beauty of a plant in a pot which decorated the entrance hall of the nursing-home. 'But what is its name, doctor? Do you know? I used to know its German and its Latin names, but I've forgotten them both.' She had a wide knowledge of plants, while I was obliged on this occasion to admit my lack of botanical education. A few minutes later I asked her under hypnosis if she now knew the name of the plant in the hall. Without any hesitation she replied; 'The German name is "*Türkenlilie*" [Turk's-cap lily]; I really *have* forgotten the Latin one.' Another time, when she was feeling in good health, she told me of a visit she had paid to the Roman Catacombs, but could not recall two technical terms; nor could I help her with them. Immediately afterwards I asked her under hypnosis which words she had in mind. But she did not know them in hypnosis either. So I said to her: 'Don't bother about them any more now, but when you are in the garden to-morrow between five and six in the afternoon - nearer six than five - they will suddenly occur to you.' Next evening, while we were talking about something which had no connection with catacombs, she suddenly burst out: "'Crypt", doctor, and "Columbarium".' 'Ah! those are the words you couldn't think of yesterday. When did they occur to you?' 'In the garden this afternoon just before I went up to my room.' I saw that she wanted to let me know in this way that she had followed out my instructions as to time exactly, as she was in the habit of leaving the garden at about six o'clock.

Thus we see that even in somnambulism she did not have access to the whole extent of her knowledge. Even in that state there was an actual and a potential consciousness. It used often to happen that when I asked her during her somnambulism, where this or that phenomenon was derived from, she would wrinkle her forehead, and after a pause would answer in a deprecatory tone: 'I don't know.' On such occasions I had made it my practice to say: 'Think a moment; it will come to mind directly'; and after a short reflection she would be able to give me the desired information. But it sometimes happened that nothing came to her mind and that I was obliged to leave her with the task of remembering it by the next day; and this never failed to occur.

In her ordinary life Frau von N. scrupulously avoided any untruthfulness, nor did she ever lie to me under hypnosis. Occasionally, however, she would give me incomplete answers and keep back part of her story until I insisted a second time on her completing it. It was usually - as in the instance quoted on p. 73 - the distaste inspired by the topic which closed her mouth in somnambulism no less than in ordinary life. Nevertheless, in spite of these restrictive traits, the impression made by her mental behaviour during somnambulism was, on the whole, one of an uninhibited unfolding of her mental powers and of a full command over her store of memories.

Though it cannot be denied that in a state of somnambulism she was highly suggestible, she was far from exhibiting a pathological absence of resistance. It can be asserted on the whole that I did not make more impression on her in that state than I might have expected to do if I were making an investigation of this kind into the psychical mechanisms of someone in full possession of his faculties who put complete confidence in what I said. The only difference was that Frau von N. was unable, in what passed as her normal state, to meet me with any such favourable mental attitude. If, as with her animal phobia, I failed to give her convincing reasons, or did not go into the psychical history of the origin of a symptom but tried to operate by the agency of authoritative suggestion, I invariably observed a strained and dissatisfied expression on her face; and when, at the end of the hypnosis, I asked her whether she would still be afraid of the animal, she would answer: 'No - since you insist.' A promise like this, based only on her obedience to me, never met with any success, any more than did the many general injunctions which I laid upon her, instead of which I might just as well have repeated the single suggestion that she should get well.

But this same person who clung so obstinately to her symptoms in the face of suggestion and would only abandon them in response to psychical analysis or personal conviction, was on the other hand as amenable as the best medium to be found in any hospital, so far as irrelevant suggestions were concerned - so far as it was a question of matters not connected with her illness. I have given instances of her post-hypnotic obedience in the course of the case history. There does not seem to me to be anything contradictory in this behaviour. Here, too, the stronger idea was bound to assert itself. If we go into the mechanism of '*idées fixes*', we find that they are based upon and supported by so many experiences operating with such intensity that we cannot be surprised to find that these ideas are able to put up a successful resistance against the opposing idea brought forward by suggestion, which is clothed with only limited powers. It would have to be a truly pathological brain from which it was possible to blow away by mere suggestion such well founded products of intense psychical events.¹

¹ I have been deeply impressed in another of my patients by this interesting contrast during somnambulism between a most far-reaching obedience in everything unconnected with the symptoms and the obstinacy with which those symptoms persist because they are deeply rooted and inaccessible to analysis. A lively and gifted girl, who had suffered for eighteen months from severe disturbances of her power of walking, was under my treatment for more than five months without my being able to help her. She was analgesic and had painful areas in both legs and a rapid tremor in her hands. She walked bent forward, dragging her legs and with short steps; she staggered as though she was a cerebellar case and, indeed, often fell down. Her temperament was strikingly cheerful. One of the leading authorities in Vienna at the time was misled by this syndrome into diagnosing her case as one of multiple sclerosis. Another specialist recognized her as a hysteric - a diagnosis which was supported by the complicated picture presented by the disease in its beginnings (pains, fainting-fits, amaurosis) - and handed her on to me for treatment. I tried to improve her gait by suggestion, manipulation of her legs under hypnosis, etc., but I had no success in spite of her being an excellent subject for somnambulism. One day, after she once more came tottering into the room, one arm supported on her father's, the other on an umbrella whose tip was already much worn down, I lost patience and shouted at her in her hypnosis: 'This has gone on too long. To-morrow morning that umbrella of yours will break in your hands and you'll have to walk without it, and from that time on you will never need an umbrella again.' I cannot imagine how I came to be so foolish as to give a suggestion to an umbrella. Afterwards I felt ashamed of myself, and did not suspect that my clever patient would save my reputation in the eyes of her father, who was a physician and was present during her hypnoses. Next day her father said to me: 'What do you think she did yesterday? We were walking along the Ringstrasse when she suddenly got into the highest spirits. She began singing - in the very middle of the street - "Ein freies Leben führen wir" ["We live a free life"] and beat time on the pavement with her umbrella and broke it.' Of course she herself had no notion that she had wittily transformed a nonsensical suggestion into a brilliantly successful one. Since her condition was not improved by assurances, commands and treatment under hypnosis, I turned to psychical analysis and requested her to tell me what emotion had preceded the onset of her illness. She answered (under hypnosis but without any signs of feeling) that a short time previously a young relative of hers had died to whom she had for many years considered herself engaged. This piece of information, however, produced no alteration whatever in her condition. Accordingly, during her next hypnosis, I told her I was quite convinced that her cousin's death had had nothing at all to do with her state, but that something else had happened which she had not mentioned. At this she gave way to the extent of letting fall a single significant phrase; but she had hardly said a word before she stopped, and her old father, who was sitting behind her, began to sob bitterly. Naturally I pressed my investigation no further; but I never saw the patient again.

It was while I was studying Frau von N.'s abulias that I began for the first time to have grave doubts about the validity of Bernheim's assertion, '*tout est dans la suggestion*' ['suggestion is everything'] and about his clever friend Delboeuf's inference: '*Comme quoi il n'y a pas d'hypnotisme*' ['That being so, there is no such thing as hypnotism']. And to this day I cannot understand how it can be supposed that by merely holding up a finger and saying once 'go to sleep' I had created in the patient the peculiar psychical state in which her memory had access to all her psychical experiences. I may have *called up* the state by my suggestion but I did not *create* it, since its features - which are, incidentally, found universally - came as such a surprise to me.

The case history makes sufficiently plain the way in which therapeutic work was carried out during somnambulism. As is the usual practice in hypnotic psychotherapy, I fought against the patient's pathological ideas by means of assurances and prohibitions, and by putting forward opposing ideas of every sort. But I did not content myself with this. I investigated the genesis of the individual symptoms so as to be able to combat the premises on which the pathological ideas were erected. In the course of such an analysis it habitually happened that the patient gave verbal utterance with the most violent agitation to matters whose accompanying affect had hitherto only found outlet as an expression of emotion. I cannot say how much of the therapeutic success each time was due to my suggesting the symptom away *in statu nascendi* and how much to my resolving the affect by abreaction, since I combined both these therapeutic factors. Accordingly, this case cannot strictly be used as evidence for the therapeutic efficacy of the cathartic procedure; at the same time I must add that only those symptoms of which I carried out a psychical analysis were really permanently removed.

The therapeutic success on the whole was considerable; but it was not a lasting one. The patient's tendency to fall ill in a similar way under the impact of fresh traumas was not got rid of. Anyone who wanted to undertake the definitive cure of a case of hysteria such as this would have to enter more thoroughly into the complex of phenomena than I attempted to do. Frau von N. was undoubtedly a personality with a severe neuropathic heredity. It seems likely that there can be no hysteria apart from a disposition of this kind. But on the other hand disposition alone does not make hysteria. There must be reasons that bring it about, and, in my opinion, these reasons must be appropriate: the aetiology is of a specific character. I have already mentioned that in Frau von N. the affects of a great number of traumatic experiences had been retained and that the lively activity of her memory brought now one and now another of these traumas to the surface of her mind. I shall now venture to put forward an explanation of the reason why she retained the affects in this way. That reason, it is true, was connected with her hereditary disposition. For, on the one hand, her feelings were very intense; she was of a vehement nature, capable of the strongest passions. On the other hand, since her husband's death, she had lived in complete mental solitude; her persecution by her relatives had made her suspicious of friends and she was jealously on guard against anyone acquiring too much influence over her actions. The circle of her duties was very wide, and she performed the whole of the mental work which they imposed on her by herself, without a friend or confidant, almost isolated from her family and handicapped by her conscientiousness, her tendency to tormenting herself and often, too, by the natural helplessness of a woman. In short the mechanism of *the retention of large sums of excitation*, apart from everything else, cannot be overlooked in this case. It was based partly on the circumstances of her life and partly on her natural disposition. Her dislike, for instance, of saying anything about herself was so great, that, as I noticed to my astonishment in 1891, none of the daily visitors to her house recognized that she was ill or were aware that I was her doctor.

Does this exhaust the aetiology of this case of hysteria? I do not think so. For at the time of her two treatments I had not yet raised in my own mind the questions which must be answered before an exhaustive explanation of such a case is possible. I am now of the opinion that there must have been some added factor to provoke the outbreak of illness precisely in these last years, considering that operative aetiological conditions had been present for many years previously. It has also struck me that amongst all the intimate information given me by the patient there was a complete absence of the sexual element, which is, after all, more liable than any other to provide occasion for traumas. It is impossible that her excitations in this field can have left no traces whatever; what I was allowed to hear was no doubt an *editio in usum delphini* [a bowdlerized edition] of her life-story. The patient behaved with the greatest and to all appearances with the most unforced sense of propriety, without a trace of prudishness. When, however, I reflect on the reserve with which she told me under hypnosis about her maid's little adventure in the hotel, I cannot help suspecting that this woman who was so passionate and so capable of strong feelings had not won her victory over her sexual needs without severe struggles, and that at times her attempts at suppressing this most powerful of all instincts had exposed her to severe mental exhaustion. She once admitted to me that she had not married again because, in view of her large fortune, she could not credit the disinterestedness of her suitors and because she would have reproached herself for damaging the prospects of her two children by a new marriage.

I must make one further remark before bringing Frau von N.'s case history to a close. Dr. Breuer and I knew her pretty well and for a fairly long time, and we used to smile when we compared her character with the picture of the hysterical psyche which can be traced from early times through the writings and the opinions of medical men. We had learnt from our observations on Frau Cécilie M. that hysteria of the severest type can exist in conjunction with gifts of the richest and most original kind - a conclusion which is, in any case, made plain beyond a doubt in the biographies of women eminent in history and literature. In the same way Frau Emmy von N. gave us an example of how hysteria is compatible with an unblemished character and a well-governed mode of life. The woman we came to know was an admirable one. The moral seriousness with which she viewed her duties, her intelligence and energy, which were no less than a man's, and her high degree of education and love of truth impressed both of us greatly; while her benevolent care for the welfare of all her dependants, her humility of mind and the refinement of her manners revealed her qualities as a true lady as well. To describe such a woman as a 'degenerate' would be to distort the meaning of that word out of all recognition. We should do well to distinguish between the concepts of 'disposition' and 'degeneracy' as applied to people; otherwise we shall find ourselves forced to admit that humanity owes a large proportion of its great achievements to the efforts of 'degenerates'.

I must confess, too, that I can see no sign in Frau von N.'s history of the 'psychical inefficiency' to which Janet attributes the genesis of hysteria. According to him the hysterical disposition consists in an abnormal restriction of the field of consciousness (due to hereditary degeneracy) which results in a disregard of whole groups of ideas and, later, to a disintegration of the ego and the organization of secondary personalities. If this were so, what remains of the ego after the withdrawal of the hysterically-organized psychical groups would necessarily also be less efficient than a normal ego; and in fact, according to Janet, the ego in hysteria is afflicted by psychical stigmata, condemned to mono-ideism and incapable of the volitional acts of ordinary life. Janet, I think, has made the mistake here of promoting what are after-effects of changes in consciousness due to hysteria to the rank of primary determinants of hysteria. The subject is one that deserves further consideration elsewhere; but in Frau von N. there was no sign of any such inefficiency. During the times of her worst states she was and remained capable of playing her part in the management of a large industrial business, of keeping a constant eye on the education of her children, of carrying on her correspondence with prominent people in the intellectual world - in short, of fulfilling her obligations well enough for the fact of her illness to remain concealed. I am inclined to believe, then, that all this involved a considerable excess of efficiency, which could perhaps not be kept up in the long run and was bound to lead to exhaustion - to a secondary '*misère psychologique*' ['psychological impoverishment']. It seems likely that disturbances of this kind in her efficiency were beginning to make themselves felt at the time when I first saw her; but however that may be, severe hysteria had been present for many years before the appearance of the symptoms of exhaustion.¹

¹ [Footnote added 1924:] I am aware that no analyst can read this case history to-day without a smile of pity. But it should be borne in mind that this was the first case in which I employed the cathartic procedure to a large extent. For this reason I shall leave the report in its original form. I shall not bring forward any of the criticisms which can so easily be made on it to-day, nor shall I attempt to fill in any of the numerous gaps in it. I will only add two things: what I afterwards discovered about the immediate aetiology of the illness and what I heard of its subsequent course.

When, as I have mentioned, I spent a few days as Frau Emmy's guest in her country house, there was a stranger present at one of the meals who clearly tried to make himself agreeable. After his departure my hostess asked me how I had liked him and added as it were in passing: 'Only imagine, the man wants to marry me!' When I took this in connection with some other remarks which she had made, but to which I had not paid sufficient attention, I was led to conclude that she was longing at that time to be married again but found an obstacle to the realization of her purpose in the existence of her two daughters, who were the heiresses of their father's fortune.

A few years later at a Scientific Congress I met a prominent physician from Frau Emmy's part of the country. I asked him if he was acquainted with the lady and knew anything of her condition. Yes, he said, he knew her, and had himself given her hypnotic treatment. She had gone through the same performance with him - and with many other doctors - as she had with me. Her condition had become very bad; she had rewarded his hypnotic treatment of her by making a remarkable recovery, but had then suddenly quarrelled with him, left him, and once more set her illness going to its full extent. It was a genuine instance of the 'compulsion to repeat'.

It was not for another quarter of a century that I once more had news of Frau Emmy. Her elder daughter - the one of whom I had earlier made such an unfavourable prognosis - approached me with a request for a report on her mother's mental condition on the strength of my former treatment of her. She was intending to take legal proceedings against her mother, whom she represented as a cruel and ruthless tyrant. It seems that she had broken off relations with both her children and refused to assist them in their financial difficulties. The daughter who wrote to me had obtained a doctor's degree and was married.

CASE 3

MISS LUCY R., AGE 30 (Freud)

At the end of the year 1892 a colleague of my acquaintance referred a young lady to me who was being treated by him for chronically recurrent suppurative rhinitis. It subsequently turned out that the obstinate persistence of her trouble was due to caries of the ethmoid bone. Latterly she had complained of some new symptoms which the well-informed physician was no longer able to attribute to a local affection. She had entirely lost her sense of smell and was almost continuously pursued by one or two subjective olfactory sensations. She found these most distressing. She was, moreover, in low spirits and fatigued, and she complained of heaviness in the head, diminished appetite and loss of efficiency.

The young lady, who was living as a governess in the house of the managing director of a factory in Outer Vienna, came to visit me from time to time in my consulting hours. She was an Englishwoman. She had a delicate constitution, with a poor pigmentation, but was in good health apart from her nasal affection. Her first statements confirmed what the physician had told me. She was suffering from depression and fatigue and was tormented by subjective sensations of smell. As regards hysterical symptoms, she showed a fairly definite general analgesia, with no loss of tactile sensibility, and a rough examination (with the hand) revealed no restriction of the visual field. The interior of her nose was completely analgesic and without reflexes; she was sensitive to tactile pressure there, but the perception proper to it as a sense-organ was absent, alike for specific stimuli and for others (e.g. ammonia or acetic acid). The purulent nasal catarrh was just then in a phase of improvement.

In our first attempts at making the illness intelligible it was necessary to interpret the subjective olfactory sensations, since they were recurrent hallucinations, as chronic hysterical symptoms. Her depression might perhaps be the affect attaching to the trauma, and it should be possible to find an experience in which these smells, which had now become subjective, had been objective. This experience must have been the trauma which the recurring sensations of smell symbolized in memory. It might be more correct to regard the recurrent olfactory hallucinations, together with the depression which accompanied them, as equivalents of a hysterical *attack*. The nature of recurrent hallucinations makes them unsuitable in point of fact for playing the part of *chronic* symptoms. But this question did not really arise in a case like this which showed only a rudimentary development. It was essential, however, that the subjective sensations of smell should have had a specialized origin of a sort which would admit of their being derived from some quite particular real object.

This expectation was promptly fulfilled. When I asked her what the smell was by which she was most constantly troubled she answered: 'A smell of burnt pudding.' Thus I only needed to assume that a smell of burnt pudding had actually occurred in the experience which had operated as a trauma. It is very unusual, no doubt, for olfactory sensations to be chosen as mnemonic symbols of traumas, but it was not difficult to account for this choice. The patient was suffering from suppurative rhinitis and consequently her attention was especially focused on her nose and nasal sensations. What I knew of the circumstances of the patient's life was limited to the fact that the two children whom she was looking after had no mother; she had died some years earlier of an acute illness.

I therefore decided to make the smell of burnt pudding the starting-point of the analysis. I will describe the course of this analysis as it might have taken place under favourable conditions. In fact, what should have been a single session spread over several. This was because the patient could only visit me in my consulting hours, when I could only devote a short time to her. Moreover, a single discussion of this sort used to extend over more than a week, since her duties would not allow her to make the long journey from the factory to my house very often. We used therefore to break our conversation off short and take up the thread at the same place next time.

Miss Lucy R. did not fall into a state of somnambulism when I tried to hypnotize her. I therefore did without somnambulism and conducted her whole analysis while she was in a state which may in fact have differed very little from a normal one.

I shall have to go into this point of my technical procedure in greater detail. When, in 1889, I visited the Nancy clinics, I heard Dr. Liébeault, the *doyen* of hypnotism, say: 'If only we had the means of putting every patient into a state of somnambulism, hypnotic therapy would be the most powerful of all.' In Bernheim's clinic it almost seemed as though such an art really existed and as though it might be possible to learn it from Bernheim. But as soon as I tried to practise this art on my own patients, I discovered that *my* powers at least were subject to severe limits, and that if somnambulism were not brought about in a patient at the first three attempts I had no means of inducing it. The percentage of cases amenable to somnambulism was very much lower in my experience than what Bernheim reported.

I was accordingly faced with the choice of either abandoning the cathartic method in most of the cases which might have been suitable for it, or of venturing on the experiment of employing that method without somnambulism and where the hypnotic influence was light or even where its existence was doubtful. It seemed to me a matter of indifference what degree of hypnosis - according to one or other of the scales that have been proposed for measuring it - was reached by this non somnambulist state; for, as we know, each of the various forms taken by suggestibility is in any case independent of the others, and the bringing about of catalepsy, automatic movements, and so on, does not work either for or against what I required for my purposes, namely that the awakening of forgotten memories should be made easier. Moreover, I soon dropped the practice of making tests to show the degree of hypnosis reached, since in quite a number of cases this roused the patients' resistance and shook their confidence in me, which I needed for carrying out the more important psychological work. Furthermore, I soon began to tire of issuing assurances and commands such as: 'You are going to sleep! . . . sleep!' and of hearing the patient, as so often happened when the degree of hypnosis was light, remonstrate with me: 'But, doctor, I'm *not* asleep', and of then having to make highly ticklish distinctions: 'I don't mean ordinary sleep; I mean hypnosis. As you see, you are hypnotized, you can't open your eyes', etc., 'and in any case, there's no need for you to go to sleep', and so on. I feel sure that many other physicians who practise psychotherapy can get out of such difficulties with more skill than I can. If so, they may adopt some procedure other than mine. It seems to me, however, that if one can reckon with such frequency on finding oneself in an embarrassing situation through the use of a particular word, one will be wise to avoid both the word and the embarrassment. When, therefore, my first attempt did not lead either to somnambulism or to a degree of hypnosis involving marked physical changes, I ostensibly dropped hypnosis, and only asked for 'concentration'; and I ordered the patient to lie down and deliberately shut his eyes as a means of achieving this 'concentration'. It is possible that in this way I obtained with only a slight effort the deepest degree of hypnosis that could be reached in the particular case.

But in doing without somnambulism I might be depriving myself of a precondition without which the cathartic method seemed unusable. For that method clearly rested on the patients in their changed state of consciousness having access to memories and being able to recognize connections which appeared not to be present in their normal state of consciousness. If the somnambulistic extension of memory were absent there could also be no possibility of establishing any determining causes which the patient could present to the physician as something unknown to him (the patient); and, of course, it is precisely the pathogenic memories which, as we have already said in our 'Preliminary Communication' are 'absent from the patients' memory, when they are in a normal psychical state, or are only present in a highly summary form'.

I was saved from this new embarrassment by remembering that I had myself seen Bernheim producing evidence that the memories of events during somnambulism are only *apparently* forgotten in the waking state and can be revived by a mild word of command and a pressure with the hand intended to indicate a different state of consciousness. He had, for instance, given a woman in a state of somnambulism a negative hallucination to the effect that he was no longer present, and had then endeavoured to draw her attention to himself in a great variety of ways, including some of a decidedly aggressive kind. He did not succeed. After she had been woken up he asked her to tell him what he had done to her while she thought he was not there. She replied in surprise that she knew nothing of it. But he did not accept this. He insisted that she could remember everything and laid his hand on her forehead to help her to recall it. And lo and behold! she ended by describing everything that she had ostensibly not perceived during her somnambulism and ostensibly not remembered in her waking state.

This astonishing and instructive experiment served as my model. I decided to start from the assumption that my patients knew everything that was of any pathogenic significance and that it was only a question of obliging them to communicate it. Thus when I reached a point at which, after asking a patient some question such as: 'How long have you had this symptom?' or: 'What was its origin?', I was met with the answer: 'I really don't know, I proceeded as follows. I placed my hand on the patient's forehead or took her head between my hands and said: 'You will think of it under the pressure of my hand. At the moment at which I relax my pressure you will see something in front of you or something will come into your head. Catch hold of it. It will be what we are looking for. - Well what have you seen or what has occurred to you?'

On the first occasions on which I made use of this procedure (it was not with Miss Lucy R.) I myself was surprised to find that it yielded me the precise results that I needed. And I can safely say that it has scarcely ever left me in the lurch since then. It has always pointed the way which the analysis should take and has enabled me to carry through every such analysis to an end without the use of somnambulism. Eventually I grew so confident that, if patients answered, 'I see nothing' or 'nothing has occurred to me', I could dismiss this as an impossibility and could assure them that they had certainly become aware of what was wanted but had refused to believe that that was so and had rejected it. I told them I was ready to repeat the procedure as often as they liked and they would see the same thing every time. I turned out to be invariably right. The patients had not yet learned to relax their critical faculty. They had rejected the memory that had come up or the idea that had occurred to them, on the ground that it was unserviceable and an irrelevant interruption; and after they had told it to me it always proved to be what was wanted. Occasionally, when, after three or four pressures, I had at last extracted the information, the patient would reply: 'As a matter of fact I knew that the first time, but it was just what I didn't want to say', or: 'I hoped that would not be it.'

This business of enlarging what was supposed to be a restricted consciousness was laborious - far more so, at least, than an investigation during somnambulism. But it nevertheless made me independent of somnambulism, and gave me insight into the motives which often determine the 'forgetting' of memories. I can affirm that this forgetting is often intentional and desired; and its success is never more than *apparent*.

I found it even more surprising perhaps that it was possible by the same procedure to bring back numbers and dates which, on the face of it, had long since been forgotten, and so to reveal how unexpectedly accurate memory can be.

The fact that in looking for numbers and dates our choice is so limited enables us to call to our help a proposition familiar to us from the theory of aphasia, namely that recognizing something is a lighter task for memory than thinking of it spontaneously. Thus, if a patient is unable to remember the year or month or day when a particular event occurred, we can repeat to him the dates of the possibly relevant years, the names of the twelve months and the thirty-one numbers of the days of the month, assuring him that when we come to the right number or the right name his eyes will open of their own accord or that he will feel which is the right one. In the great majority of cases the patient will in fact decide on a particular date. Quite often (as in the case of Frau Căcilie M.) it is possible to prove from documents belonging to the period in question that the date has been recognized correctly; while in other cases and on other occasions the indisputable accuracy of the date thus chosen can be inferred from the context of the facts remembered. For instance, after a patient had had her attention drawn to the date which had been arrived at by this 'counting over' method, she said: 'Why, that's my father's birthday!' and added: 'Of course! It was because it was his birthday that I was expecting the event we were talking about.'

Here I can only touch upon the theme in passing. The conclusion I drew from all these observations was that experiences which have played an important pathogenic part, and all their subsidiary concomitants, are accurately retained in the patient's memory even when they seem to be forgotten - when he is unable to call them to mind.¹

¹ As an example of the technique which I have described above of carrying out investigations in non-somnambulist states - that is, where there is no extension of consciousness - I will describe an instance which I happen to have analysed in the course of the last few days. I was treating a woman of thirty-eight, suffering from anxiety neurosis (agoraphobia, attacks of fear of death, etc.). Like so many such patients, she had a disinclination to admitting that she had acquired these troubles in her married life and would have liked to push them back into her early youth. Thus she told me that she was seventeen when she had had a first attack of dizziness, with anxiety and feelings of faintness, in the street in her small native town, and that these attacks had recurred from time to time, till a few years ago they had given place to her present disorder. I suspected that these first attacks of dizziness, in which the anxiety faded more and more into the background, were hysterical and I made up my mind to embark on an analysis of them. To begin with she only knew that this first attack came over her while she was out shopping in the principal street. 'What were you going to buy?' - 'Different things, I believe; they were for a ball I had been invited to.' - 'When was this ball to take place?' - 'Two days later, I think.' - 'Something must have happened to agitate you a few days before, something that made an impression on you.' - 'I can't think of anything. After all, it was twenty-one years ago.' - 'That makes no difference; you will remember all the same. I shall press on your head, and when I relax the pressure, you will think of something or see something, and you must tell me what that is.' I went through this procedure; but she remained silent. 'Well, has nothing occurred to you?' - 'I have thought of something, but it can't have any connection with this.' - 'Tell it to me anyway.' - 'I thought of a friend of mine, a girl, who is dead. But she died when I was eighteen - a year later, that is.' - 'We shall see. Let's stick to this point. What about this friend of yours?' - 'Her death was a great shock to me, as I used to see a lot of her. A few weeks earlier another girl had died, and that had made a great stir in the town. So after all, I must have been seventeen at the time.' - 'There, you see, I told you we could rely on the things that come into your head under the pressure of my hand. Now, can you remember what you were thinking about when you felt dizzy in the street?' - ('I wasn't thinking of anything; I only felt dizzy.') - 'That's not possible. States like that never happen without being accompanied by some idea. I shall press once more and the thought you had will come back to you.... Well, what has occurred to you?' - 'The idea that I am the third.' - 'What does that mean?' - 'When I got the attack of dizziness I must have thought: "Now I am dying, like the other two girls." ' - 'That was the idea, then. As you were having the attack you thought of your friend. So her death must have made a great impression on you.' - 'Yes, it did. I can remember now that when I heard of her death I felt it was dreadful to be going to a ball, while she was dead. But I was looking forward so much to the ball and was so busy with preparations for it; I didn't want to think of what had happened at all.' (We may observe here a deliberate repression from consciousness, which rendered the patient's memory of her friend pathogenic.)

The attack was now to some extent explained. But I still required to know of some precipitating factor which had provoked the memory at that particular time. I formed what happened to be a lucky conjecture. 'Do you remember the exact street you were walking along just then?' - 'Certainly. It was the principal street, with its old houses. I can see them now.' - 'And where was it that your friend lived?' - 'In a house in the same street. I had just passed it, and I had the attack a couple of houses further on.' - 'So when you went by the house it reminded you of your dead friend, and you were once more overcome by the contrast which you did not want to think of.'

I was still not satisfied. There might, I thought, be something else at work as well that had aroused or reinforced the hysterical disposition of a girl who had till then been normal. My suspicions turned to her monthly periods as an

Studies On Hysteria

appropriate factor, and I asked: 'Do you know at what time in the month your period came on?' The question was not a welcome one. 'Do you expect me to know that, too? I can only tell you that I had them very seldom then and very irregularly. When I was seventeen I only had one once.' - 'Very well, then, we will find out when this once was by counting over.' I did the counting over, and she decided definitely on one particular month and hesitated between two days immediately preceding the date of a fixed holiday. 'Does that fit in somehow with the date of the ball?' She answered sheepishly: 'The ball was on the holiday. And now I remember, too, what an impression it made on me that my only period that year should have had to come on just before the ball. It was my first ball.'

There is no difficulty now in reconstructing the interconnection between the events, and we can now see into the mechanism of this hysterical attack. It is true that the achievement of this result had been a laborious business. It required complete confidence in my technique on my side, and the occurrence to the patient of a few key ideas, before it was possible to re-awaken, after an interval of twenty-one years, these details of a forgotten experience in a sceptical person who was, in fact, in a waking state. But once all this had been gone through, the whole thing fitted together.

After this long but unavoidable digression I will return to the case of Miss Lucy R. As I have said, then, my attempts at hypnosis with her did not produce somnambulism. She simply lay quietly in a state open to some mild degree of influence, with her eyes closed all the time, her features somewhat rigid, and without moving hand or foot. I asked her if she could remember the occasion on which she first had the smell of burnt pudding. 'Oh yes, I know exactly. It was about two months ago, two days before my birthday. I was with the children in the schoolroom and was playing at cooking with them' (they were two little girls). 'A letter was brought in that had just been left by the postman. I saw from the postmark and the handwriting that it was from my mother in Glasgow and wanted to open it and read it; but the children rushed at me, tore the letter out of my hands and cried: "No, you shan't read it now! It must be for your birthday; we'll keep it for you!" While the children were having this game with me there was suddenly a strong smell. They had forgotten the pudding they were cooking and it was getting burnt. Ever since this I have been pursued by the smell. It is there all the time and becomes stronger when I am agitated.'

'Do you see this scene clearly before your eyes?' - 'As large as life, just as I experienced it.' - 'What could there be about it that was so agitating?' - 'I was moved because the children were so affectionate to me.' - 'Weren't they always?' - 'Yes - but just when I got the letter from my mother.' - 'I don't understand why there is a contrast between the children's affection and your mother's letter, for that's what you seem to be suggesting.' - 'I was intending to go back to my mother's, and the thought of leaving the dear children made me feel so sad.' - 'What's wrong with your mother? Has she been feeling lonely and sent for you? Or was she ill at the time, and were you expecting news of her?' - 'No; she isn't very strong, but she's not exactly ill, and she has a companion with her.' - 'Then why must you leave the children?' - 'I couldn't bear it any longer in the house. The housekeeper, the cook and the French governess seem to have thought that I was putting myself above my station. They joined in a little intrigue against me and said all sorts of things against me to the children's grandfather, and I didn't get as much support as I had expected from the two gentlemen when I complained to them. So I gave notice to the Director' (the children's father). 'He answered in a very friendly way that I had better think the matter over for a couple of weeks before I finally gave him my decision. I was in this state of uncertainty at the time, and thought I should be leaving the house; but I have stayed on.' - 'Was there something particular, apart from their fondness for you, which attached you to the children?' - 'Yes. Their mother was a distant relation of my mother's, and I had promised her on her death-bed that I would devote myself with all my power to the children, that I would not leave them and that I would take their mother's place with them. In giving notice I had broken this promise.'

This seemed to complete the analysis of the patient's subjective sensation of smell. It had turned out in fact to have been an objective sensation originally, and one which was intimately associated with an experience - a little scene - in which opposing affects had been in conflict with each other: her regret at leaving the children and the slights which were nevertheless urging her to make up her mind to do so. Her mother's letter had not unnaturally reminded her of her reasons for this decision, since it was her intention to join her mother on leaving here. The conflict between her affects had elevated the moment of the letter's arrival into a trauma, and the sensation of smell that was associated with this trauma persisted as its symbol. It was still necessary to explain why, out of all the sense-perceptions afforded by the scene, she had chosen this smell as a symbol. I was already prepared, however, to use the chronic affection of her nose as a help in explaining the point. In response to a direct question she told me that just at that time she had once more been suffering from such a heavy cold in the nose that she could hardly smell anything. Nevertheless, while she was in her state of agitation she perceived the smell of the burnt pudding, which broke through the organically determined loss of her sense of smell.

But I was not satisfied with the explanation thus arrived at. It all sounded highly plausible, but there was something that I missed, some adequate reason why these agitations and this conflict of affects should have led to hysteria rather than anything else. Why had not the whole thing remained on the level of normal psychical life? In other words, what was the justification for the conversion which occurred? Why did she not always call to mind the scene itself, instead of the associated sensation which she singled out as a symbol of the recollection. Such questions might be over-curious and superfluous if we were dealing with a hysteric of long standing in whom the mechanism of conversion was habitual. But it was not until this trauma, or at any rate this small tale of trouble, that the girl had acquired hysteria.

Now I already knew from the analysis of similar cases that before hysteria can be acquired for the first time one essential condition must be fulfilled: an idea must be *intentionally repressed from consciousness* and excluded from associative modification. In my view this intentional repression is also the basis for the conversion, whether total or partial, of the sum of excitation. The sum of excitation, being cut off from psychical association, finds its way all the more easily along the wrong path to a somatic innervation. The basis for repression itself can only be a feeling of unpleasure, the incompatibility between the single idea that is to be repressed and the dominant mass of ideas constituting the ego. The repressed idea takes its revenge, however, by becoming pathogenic.

I accordingly inferred from Miss Lucy R.'s having succumbed to hysterical conversion at the moment in question that among the determinants of the trauma there must have been one which she had sought intentionally to leave in obscurity and had made efforts to forget. If her fondness for the children and her sensitiveness on the subject of the other members of the household were taken together, only one conclusion could be reached. I was bold enough to inform my patient of this interpretation. I said to her: 'I cannot think that these are all the reasons for your feelings about the children. I believe that really you are in love with your employer, the Director, though perhaps without being aware of it yourself, and that you have a secret hope of taking their mother's place in actual fact. And then we must remember the sensitiveness you now feel towards the servants, after having lived with them peacefully for years. You're afraid of their having some inkling of your hopes and making fun of you.'

She answered in her usual laconic fashion: 'Yes, I think that's true.' - 'But if you knew you loved your employer why didn't you tell me?' - 'I didn't know - or rather I didn't want to know. I wanted to drive it out of my head and not think of it again; and I believe latterly I have succeeded.'¹ 'Why is it that you were unwilling to admit this inclination? Were you ashamed of loving a man?' - 'Oh no, I'm not unreasonably prudish. We're not responsible for our feelings, anyhow. It is distressing to me only because he is my employer and I am in his service and live in his house. I don't feel the same complete independence towards him that I could towards anyone else. And then I am only a poor girl and he is such a rich man of good family. People would laugh at me if they had any idea of it.'

¹ I have never managed to give a better description than this of the strange state of mind in which one knows and does not know a thing at the same time. It is clearly impossible to understand it unless one has been in such a state oneself. I myself have had a very remarkable experience of this sort, which is still clearly before me. If I try to recollect what went on in my mind at the time I can get hold of very little. What happened was that I saw something which did not fit in at all with my expectation; yet I did not allow what I saw to disturb my fixed plan in the least, though the perception should have put a stop to it. I was unconscious of any contradiction in this; nor was I aware of my feelings of repulsion, which must nevertheless undoubtedly have been responsible for the perception producing no psychical effect. I was afflicted by that blindness of the seeing eye which is so astonishing in the attitude of mothers to their daughters, husbands to their wives and rulers to their favourites.

She now showed no resistance to throwing light on the origin of this inclination. She told me that for the first few years she had lived happily in the house, carrying out her duties and free from any unfulfillable wishes. One day, however, her employer, a serious, overworked man whose behaviour towards her had always been reserved, began a discussion with her on the lines along which children should be brought up. He unbent more and was more cordial than usual and told her how much he depended on her for looking after his orphaned children; and as he said this he looked at her meaningly. . . . Her love for him had begun at that moment, and she even allowed herself to dwell on the gratifying hopes which she had based on this talk. But when there was no further development, and when she had waited in vain for a second hour's intimate exchange of views, she decided to banish the whole business from her mind. She entirely agreed with me that the look she had caught during their conversation had probably sprung from his thoughts about his wife, and she recognized quite clearly that there was no prospect of her feelings for him meeting with any return.

I expected that this discussion would bring about a fundamental change in her condition. But for the time being this did not occur. She continued to be in low spirits and depressed. She felt somewhat refreshed in the mornings by a course of hydropathic treatment which I prescribed for her at the same time. The smell of burnt pudding did not disappear completely, though it became less frequent and weaker. It only came on, she said, when she was very much agitated. The persistence of this mnemonic symbol led me to suspect that, in addition to the main scene, it had taken over the representation of the many minor traumas subsidiary to that scene. We therefore looked about for anything else that might have to do with the scene of the burnt pudding; we went into the subject of the domestic friction, the grandfather's behaviour, and so on, and as we did so the burnt smell faded more and more. During this time, too, the treatment was interrupted for a considerable while, owing to a fresh attack of her nasal disorder, and this now led to the discovery of the caries of the ethmoid.

On her return she reported that at Christmas she had received a great many presents from the two gentlemen of the house and even from the servants, as though they were all anxious to make it up with her and to wipe out her memory of the conflicts of the last few months. But these signs of goodwill had not made any impression on her.

When I enquired once more about the smell of burnt pudding, she informed me that it had quite disappeared but that she was being bothered by another, similar smell, resembling cigar-smoke. It had been there earlier as well, she thought, but had, as it were, been covered by the smell of the pudding. Now it had emerged by itself.

I was not very well satisfied with the results of the treatment. What had happened was precisely what is always brought up against purely symptomatic treatment: I had removed one symptom only for its place to be taken by another. Nevertheless, I did not hesitate to set about the task of getting rid of this new mnemonic symbol by analysis.

But this time she did not know where the subjective olfactory sensation came from - on what important occasion it had been an objective one. 'People smoke every day in our house,' she said, 'and I really don't know whether the smell I notice refers to some special occasion.' I then insisted that she should try to remember under the pressure of my hand. I have already mentioned that her memories had the quality of plastic vividness, that she was a 'visual' type. And in fact, at my insistence, a picture gradually emerged before her, hesitatingly and piecemeal to begin with. It was the dining-room in her house, where she was waiting with the children for the two gentlemen to return to luncheon from the factory. 'Now we are all sitting round the table, the gentlemen, the French governess, the housekeeper, the children and myself. But that's like what happens every day.' - 'Go on looking at the picture; it will develop and become more specialized.' - 'Yes, there is a guest. It's the chief accountant. He's an old man and he is as fond of the children as though they were his own grandchildren. But he comes to lunch so often that there's nothing special in that either.' - 'Be patient and just keep looking at the picture; something's sure to happen.' - 'Nothing's happening. We're getting up from the table; the children say their good-byes, and they go upstairs with us as usual to the second floor.' - 'And then?' - 'It is a special occasion, after all. I recognize the scene now. As the children say good-bye, the accountant tries to kiss them. My employer flares up and actually shouts at him: "Don't kiss the children!" I feel a stab at my heart; and as the gentlemen are already smoking, the cigar-smoke sticks in my memory.'

This, then, was a second and deeper-lying scene which, like the first, operated as a trauma and left a mnemonic symbol behind it. But to what did this scene owe its effectiveness? 'Which of the two scenes was the earlier,' I asked, 'this one or the one with the burnt pudding?' - 'The scene I have just told you about was the earlier, by almost two months.' - 'Then why did you feel this stab when the children's father stopped the old man? His reprimand wasn't aimed at you.' - 'It wasn't right of him to shout at an old man who was a valued friend of his and, what's more, a guest. He could have said it quietly.' - 'So it was only the violent way he put it that hurt you? Did you feel embarrassed on his account? Or perhaps you thought: "If he can be so violent about such a small thing with an old friend and guest, how much more so might he be with me if I were his wife".' - 'No, that's not it.' - 'But it had to do with his violence, hadn't it?' - 'Yes, about the children being kissed. He has never liked that.'

And now, under the pressure of my hand, the memory of a third and still earlier scene emerged, which was the really operative trauma and which had given the scene with the chief accountant its traumatic effectiveness. It had happened a few months earlier still that a lady who was an acquaintance of her employer's came to visit them, and on her departure kissed the two children on the mouth. Their father, who was present, managed to restrain himself from saying anything to the lady, but after she had gone, his fury burst upon the head of the unlucky governess. He said he held her responsible if anyone kissed the children on the mouth, that it was her duty not to permit it and that she was guilty of a dereliction of duty if she allowed it; if it ever happened again he would entrust his children's upbringing to other hands. This had happened at a time when she still thought he loved her, and was expecting a repetition of their first friendly talk. The scene had crushed her hopes. She had said to herself: 'If he can fly out at me like, this and make such threats over such a trivial matter, and one for which, moreover, I am not in the least responsible, I must have made a mistake. He can never have had any warm feelings for me, or they would have taught him to treat me with more consideration.' - It was obviously the recollection of this distressing scene which had come to her when the chief accountant had tried to kiss the children and had been reprimanded by their father.

After this last analysis, when, two days later, Miss Lucy visited me once more, I could not help asking her what had happened to make her so happy. She was as though transfigured. She was smiling and carried her head high. I thought for a moment that after all I had been wrong about the situation, and that the children's governess had become the Director's fiancée. But she dispelled my notion. 'Nothing has happened. It's just that you don't know me. You have only seen me ill and depressed. I'm always cheerful as a rule. When I woke yesterday morning the weight was no longer on my mind, and since then I have felt well.' - 'And what do you think of your prospects in the house?' - 'I am quite clear on the subject. I know I have none, and I shan't make myself unhappy over it.' - 'And will you get on all right with the servants now?' - 'I think my own oversensitiveness was responsible for most of that.' - 'And are you still in love with your employer?' - 'Yes, I certainly am, but that makes no difference. After all, I can have thoughts and feelings to myself.'

I then examined her nose and found that its sensitivity to pain and reflex excitability had been almost completely restored. She was also able to distinguish between smells, though with uncertainty and only if they were strong. I must leave it an open question, however, how far her nasal disorder may have played a part in the impairment of her sense of smell.

This treatment lasted in all for nine weeks. Four months later I met the patient by chance in one of our summer resorts. She was in good spirits and assured me that her recovery had been maintained.

DISCUSSION

I am not inclined to under-estimate the importance of the case that I have here described, even though the patient was suffering only from a slight and mild hysteria and though only a few symptoms were involved. On the contrary it seems to me an instructive fact that even an illness such as this, so unproductive when regarded as a neurosis, called for so many psychical determinants. Indeed, when I consider this case history more closely, I am tempted to regard it as a model instance of one particular type of hysteria, namely the form of this illness which can be acquired even by a person of sound heredity, as a result of appropriate experiences. It should be understood that I do not mean by this a hysteria which is independent of *any* pre-existing disposition. It is probable that no such hysteria exists. But we do not recognize a disposition of this sort in a subject until he has actually become a hysteric; for previously there was no evidence of its existence. A neuropathic disposition, as generally understood, is something different. It is already marked out before the onset of the illness by the amount of the subject's hereditary taint or the sum of his individual psychical abnormalities. So far as my information goes, there was no trace in Miss Lucy R. of either of these factors. Her hysteria can therefore be described as an acquired one, and it presupposed nothing more than the possession of what is probably a very widespread proclivity - the proclivity to acquire hysteria. We have as yet scarcely a notion of what the features of this proclivity may be. In cases of this kind, however, the main emphasis falls upon the nature of the trauma, though taken in conjunction, of course, with the subject's reaction to it. It turns out to be a *sine qua non* for the acquisition of hysteria that an incompatibility should develop between the ego and some idea presented to it. I hope to be able to show elsewhere how different neurotic disturbances arise from the different methods adopted by the 'ego' in order to escape from this incompatibility. The hysterical method of defence - for which, as we have seen, the possession of a particular proclivity is necessary - lies in the conversion of the excitation into a somatic innervation; and the advantage of this is that the incompatible idea is repressed from the ego's consciousness. In exchange, that consciousness now contains the physical reminiscence which has arisen through conversion (in our case, the patient's subjective sensations of smell) and suffers from the affect which is more or less clearly attached to precisely that reminiscence. The situation which has thus been brought about is now not susceptible to further change; for the incompatibility which would have called for a removal of the affect no longer exists, thanks to the repression and conversion. Thus the mechanism which produces hysteria represents on the one hand an act of moral cowardice and on the other a defensive measure which is at the disposal of the ego. Often enough we have to admit that fending off increasing excitations by the generation of hysteria is, in the circumstances, the most expedient thing to do; more frequently, of course, we shall conclude that a greater amount of moral courage would have been of advantage to the person concerned.

The actual traumatic moment, then, is the one at which the incompatibility forces itself upon the ego and at which the latter decides on the repudiation of the incompatible idea. That idea is not annihilated by a repudiation of this kind, but merely repressed into the unconscious. When this process occurs for the first time there comes into being a nucleus and centre of crystallization for the formation of a psychical group divorced from the ego - a group around which everything which would imply an acceptance of the incompatible idea subsequently collects. The splitting of consciousness in these cases of acquired hysteria is accordingly a deliberate and intentional one. At least it is often *introduced* by an act of volition; for the actual outcome is something different from what the subject intended. What he wanted was to do away with an idea, as though it had never appeared, but all he succeeds in doing is to isolate it psychically.

In the history of our present patient the traumatic moment was the moment of her employer's outburst against her about his children being kissed by the lady. For a time, however, that scene had no manifest effect. (It may be that her oversensitiveness and low spirits began from it, but I cannot say.) Her hysterical symptoms did not start until later, at moments which may be described as 'auxiliary'. The characteristic feature of such an auxiliary moment is, I believe, that the two divided psychical groups temporarily converge in it, as they do in the extended consciousness which occurs in somnambulism. In Miss Lucy R.'s case the first of the auxiliary moments, at which conversion took place, was the scene at table when the chief accountant tried to kiss the children. Here the traumatic memory was playing a part: she did not behave as though she had got rid of everything connected with her devotion to her employer. (In the history of other cases these different moments coincide; conversion occurs as an immediate effect of the trauma.)

The second auxiliary moment repeated the mechanism of the first one fairly exactly. A powerful impression temporarily reunited the patient's consciousness, and conversion once more took the path which had been opened out on the first occasion. It is interesting to notice that the second symptom to develop masked the first, so that the first was not clearly perceived until the second had been cleared out of the way. It also seems to me worth while remarking upon the reversed course which had to be followed by the analysis as well. I have had the same experience in a whole number of cases; the symptoms that had arisen later masked the earlier ones, and the key to the whole situation lay only in the last symptom to be reached by the analysis.

The therapeutic process in this case consisted in compelling the psychical group that had been split off to unite once more with the ego-consciousness. Strangely enough, success did not run *pari passu* with the amount of work done. It was only when the last piece of work had been completed that recovery suddenly took place.

CASE 4

KATHARINA ---- (Freud)

In the summer vacation of the year 189-- I made an excursion into the Hohe Tauern so that for a while I might forget medicine and more particularly the neuroses. I had almost succeeded in this when one day I turned aside from the main road to climb a mountain which lay somewhat apart and which was renowned for its views and for its well-run refuge hut. I reached the top after a strenuous climb and, feeling refreshed and rested, was sitting deep in contemplation of the charm of the distant prospect. I was so lost in thought that at first I did not connect it with myself when these words reached my ears: 'Are you a doctor, sir?' But the question was addressed to me, and by the rather sulky-looking girl of perhaps eighteen who had served my meal and had been spoken to by the landlady, as 'Katharina'. To judge by her dress and bearing, she could not be a servant, but must no doubt be a daughter or relative of the landlady's.

Coming to myself I replied: 'Yes, I'm a doctor: but how did you know that?'

'You wrote your name in the Visitors' Book, sir. And I thought if you had a few moments to spare . . . The truth is, sir, my nerves are bad. I went to see a doctor in L-- about them and he gave me something for them; but I'm not well yet.'

So there I was with the neuroses once again - for nothing else could very well be the matter with this strong, well-built girl with her unhappy look. I was interested to find that neuroses could flourish in this way at a height of over 6,000 feet; I questioned her further therefore. I report the conversation that followed between us just as it is impressed on my memory and I have not altered the patient's dialect.

'Well, what is it you suffer from?'

'I get so out of breath. Not always. But sometimes it catches me so that I think I shall suffocate.'

This did not, at first sight, sound like a nervous symptom. But soon it occurred to me that probably it was only a description that stood for an anxiety attack: she was choosing shortness of breath out of the complex of sensations arising from anxiety and laying undue stress on that single factor.

'Sit down here. What is it like when you get "out of breath"?'

'It comes over me all at once. First of all it's like something pressing on my eyes. My head gets so heavy, there's a dreadful buzzing, and I feel so giddy that I almost fall over. Then there's something crushing my chest so that I can't get my breath.'

'And you don't notice anything in your throat?'

'My throat's squeezed together as though I were going to choke.'

'Does anything else happen in your head?'

'Yes, there's a hammering, enough to burst it.'

'And don't you feel at all frightened while this is going on?'

'I always think I'm going to die. I'm brave as a rule and go about everywhere by myself - into the cellar and all over the mountain. But on a day when that happens I don't dare to go anywhere; I think all the time someone's standing behind me and going to catch hold of me all at once.'

So it was in fact an anxiety attack, and introduced by the signs of a hysterical 'aura' - or, more correctly, it was a hysterical attack the content of which was anxiety. Might there not probably be some other content as well?

'When you have an attack do you think of something and always the same thing? or do you see something in front of you?'

'Yes. I always see an awful face that looks at me in a dreadful way, so that I 'm frightened.'

Perhaps this might offer a quick means of getting to the heart of the matter.

'Do you recognize the face? I mean, is it a face that you've really seen some time?'

'No.'

'Do you know what your attacks come from?'

'No.'

'When did you first have them?'

'Two years ago, while I was still living on the other mountain with my aunt. (She used to run a refuge hut there, and we moved here eighteen months ago.) But they keep on happening.'

Was I to make an attempt at an analysis? I could not venture to transplant hypnosis to these altitudes, but perhaps I might succeed with a simple talk. I should have to try a lucky guess. I had found often enough that in girls anxiety was a consequence of the horror by which a virginal mind is overcome when it is faced for the first time with the world of sexuality.¹

So I said: 'If you don't know, I'll tell you how / think you got your attacks. At that time, two years ago, you must have seen or heard something that very much embarrassed you, and that you'd much rather not have seen.'

'Heavens, yes!' she replied, 'that was when I caught my uncle with the girl, with Franziska, my cousin.'

'What's this story about a girl? Won't you tell me all about it?'

'You can say *anything* to a doctor, I suppose. Well, at that time, you know, my uncle - the husband of the aunt you've seen here - kept the inn on the ---kogel. Now they're divorced, and it's my fault they were divorced, because it was through me that it came out that he was carrying on with Franziska.'

'And how did you discover it?'

'This way. One day two years ago some gentlemen had climbed the mountain and asked for something to eat. My aunt wasn't at home, and Franziska, who always did the cooking, was nowhere to be found. And my uncle was not to be found either. We looked everywhere, and at last Alois, the little boy, my cousin, said: "Why, Franziska must be in Father's room!" And we both laughed; but we weren't thinking anything bad. Then we went to my uncle's room but found it locked. That seemed strange to me. Then Alois said: "There's a window in the passage where you can look into the room." We went into the passage; but Alois wouldn't go to the window and said he was afraid. So I said: "You silly boy! I'll go, I'm not a bit afraid." And I had nothing bad in my mind. I looked in. The room was rather dark, but I saw my uncle and Franziska; he was lying on her.'

¹ I will quote here the case in which I first recognized this causal connection. I was treating a young married woman who was suffering from a complicated neurosis and, once again, was unwilling to admit that her illness arose from her married life. She objected that while she was still a girl she had had attacks of anxiety, ending in fainting fits. I remained firm. When we had come to know each other better she suddenly said to me one day: 'I'll tell you now how I came by my attacks of anxiety when I was a girl. At that time I used to sleep in a room next to my parents'; the door was left open and a night-light used to burn on the table. So more than once I saw my father get into bed with my mother and heard sounds that greatly excited me. It was then that my attacks came on.'

'Well?'

'I came away from the window at once, and leant up against the wall and couldn't get my breath - just what happens to me since. Everything went blank, my eyelids were forced together and there was a hammering and buzzing in my head.'

'Did you tell your aunt that very same day?'

'Oh no, I said nothing.'

'Then why were you so frightened when you found them together? Did you understand it? Did you know what was going on?'

'Oh no. I didn't understand anything at that time. I was only sixteen. I don't know what I was frightened about.'

'Fräulein Katharina, if you could remember now what was happening in you at that time, when you had your first attack, what you thought about it - it would help you.'

'Yes, if I could. But I was so frightened that I've forgotten everything.'

(Translated into the terminology of our 'Preliminary Communication', this means: 'The affect itself created a hypnoid state, whose products were then cut off from associative connection with the ego-consciousness.')

'Tell me, Fräulein. Can it be that the head that you always see when you lose your breath is Franziska's head, as you saw it then?'

'Oh no, she didn't look so awful. Besides, it's a man's head.'

'Or perhaps your uncle's?'

'I didn't see his face as clearly as that. It was too dark in the room. And why should he have been making such a dreadful face just then?'

'You're quite right.'

(The road suddenly seemed blocked. Perhaps something might turn up in the rest of her story.)

‘And what happened then?’

‘Well, those two must have heard a noise, because they came out soon afterwards. I felt very bad the whole time. I always kept thinking about it. Then two days later it was a Sunday and there was a great deal to do and I worked all day long. And on the Monday morning I felt giddy again and was sick, and I stopped in bed and was sick without stopping for three days.’

We had often compared the symptomatology of hysteria with a pictographic script which has become intelligible after the discovery of a few bilingual inscriptions. In that alphabet being sick means disgust. So I said: ‘If you were sick three days later, I believe that means that when you looked into the room you felt disgusted.’

‘Yes, I’m sure I felt disgusted,’ she said reflectively, ‘but disgusted at what?’

‘Perhaps you saw something naked? What sort of state were they in?’

‘It was too dark to see anything; besides they both of them had their clothes on. Oh, if only I knew what it was I felt disgusted at!’

I had no idea either. But I told her to go on and tell me whatever occurred to her, in the confident expectation that she would think of precisely what I needed to explain the case.

Well, she went on to describe how at last she reported her discovery to her aunt, who found that she was changed and suspected her of concealing some secret. There followed some very disagreeable scenes between her uncle and aunt, in the course of which the children came to hear a number of things which opened their eyes in many ways and which it would have been better for them not to have heard. At last her aunt decided to move with her children and niece and take over the present inn, leaving her uncle alone with Franziska, who had meanwhile become pregnant. After this, however, to my astonishment she dropped these threads and began to tell me two sets of older stories, which went back two or three years earlier than the traumatic moment. The first set related to occasions on which the same uncle had made sexual advances to her herself, when she was only fourteen years old. She described how she had once gone with him on an expedition down into the valley in the winter and had spent the night in the inn there. He sat in the bar drinking and playing cards, but she felt sleepy and went up to bed early in the room they were to share on the upper floor. She was not quite asleep when he came up; then she fell asleep again and woke up suddenly ‘feeling his body’ in the bed. She jumped up and remonstrated with him: ‘What are you up to, Uncle? Why don’t you stay in your own bed?’ He tried to pacify her: ‘Go on, you silly girl, keep still. You don’t know how nice it is.’ - ‘I don’t like your “nice” things; you don’t even let one sleep in peace.’ She remained standing by the door, ready to take refuge outside in the passage, till at last he gave up and went to sleep himself. Then she went back to her own bed and slept till morning. From the way in which she reported having defended herself it seems to follow that she did not clearly recognize the attack as a sexual one. When I asked her if she knew what he was trying to do to her, she replied: ‘Not at the time.’ It had become clear to her much later on, she said; she had resisted because it was unpleasant to be disturbed in one’s sleep and ‘because it wasn’t nice’.

I have been obliged to relate this in detail, because of its great importance for understanding everything that followed. - She went on to tell me of yet other experiences of somewhat later date: how she had once again had to defend herself against him in an inn when he was completely drunk, and similar stories. In answer to a question as to whether on these occasions she had felt anything resembling her later loss of breath, she answered with decision that she had every time felt the pressure on her eyes and chest, but with nothing like the strength that had characterized the scene of discovery.

Immediately she had finished this set of memories she began to tell me a second set, which dealt with occasions on which she had noticed something between her uncle and Franziska. Once the whole family had spent the night in their clothes in a hay loft and she was woken up suddenly by a noise; she thought she noticed that her uncle, who had been lying between her and Franziska, was turning away, and that Franziska was just lying down. Another time they were stopping the night at an inn at the village of N--; she and her uncle were in one room and Franziska in an adjoining one. She woke up suddenly in the night and saw a tall white figure by the door, on the point of turning the handle: 'Goodness, is that you, Uncle? What are you doing at the door?' - 'Keep quiet. I was only looking for something.' - 'But the way out's by the *other* door.' - 'I'd just made a mistake' . . . and so on.

I asked her if she had been suspicious at that time. 'No, I didn't think anything about it; I only just noticed it and thought no more about it.' When I enquired whether she had been frightened on these occasions too, she replied that she thought so, but she was not so sure of it this time.

At the end of these two sets of memories she came to a stop, She was like someone transformed. The sulky, unhappy face had grown lively, her eyes were bright, she was lightened and exalted. Meanwhile the understanding of her case had become clear to me. The later part of what she had told me, in an apparently aimless fashion, provided an admirable explanation of her behaviour at the scene of the discovery. At that time she had carried about with her two sets of experiences which she remembered but did not understand, and from which she drew no inferences. When she caught sight of the couple in intercourse, she at once established a connection between the new impression and these two sets of recollections, she began to understand them and at the same time to fend them off. There then followed a short period of working-out, of 'incubation', after which the symptoms of conversion set in, the vomiting as a substitute for moral and physical disgust. This solved the riddle. She had not been disgusted by the sight of the two people but by the memory which that sight had stirred up in her. And, taking everything into account, this could only be the memory of the attempt on her at night when she had 'felt her uncle's body'.

So when she had finished her confession I said to her: 'I know now what it was you thought when you looked into the room. You thought: "Now he's doing with her what he wanted to do with me that night and those other times." That was what you were disgusted at, because you remembered the feeling when you woke up in the night and felt his body.'

'It may well be,' she replied, 'that that was what I was disgusted at and that that was what I thought.'

'Tell me just one thing more. You're a grown-up girl now and know all sorts of things . . .'

'Yes, now I am.'

'Tell me just one thing. What part of his body was it that you felt that night?'

But she gave me no more definite answer. She smiled in an embarrassed way, as though she had been found out, like someone who is obliged to admit that a fundamental position has been reached where there is not much more to be said. I could imagine what the tactile sensation was which she had later learnt to interpret. Her facial expression seemed to me to be saying that she supposed that I was right in my conjecture. But I could not penetrate further, and in any case I owed her a debt of gratitude for having made it so much easier for me to talk to her than to the prudish ladies of my city practice, who regard whatever is natural as shameful.

Thus the case was cleared up. - But stop a moment! What about the recurrent hallucination of the head, which appeared during her attacks and struck terror into her? Where did it come from? I proceeded to ask her about it, and, as though *her* knowledge, too, had been extended by our conversation, she promptly replied: 'Yes, I know now. The head is my uncle's head - I recognize it now - but not from *that* time. Later, when all the disputes had broken out, my uncle gave way to a senseless rage against me. He kept saying that it was all my fault: if I hadn't chattered, it would never have come to a divorce. He kept threatening he would do something to me; and if he caught sight of me at a distance his face would get distorted with rage and he would make for me with his hand raised. I always ran away from him, and always felt terrified that he would catch me some time unawares. The face I always see now is his face when he was in a rage.'

This information reminded me that her first hysterical symptom, the vomiting, had passed away; the anxiety attack remained and acquired a fresh content. Accordingly, what we were dealing with was a hysteria which had to a considerable extent been abreacted. And in fact she had reported her discovery to her aunt soon after it happened.

'Did you tell your aunt the other stories - about his making advances to you?'

'Yes. Not at once, but later on, when there was already talk of a divorce. My aunt said: "We'll keep that in reserve. If he causes trouble in the Court, we'll say that too."'

I can well understand that it should have been precisely this last period - when there were more and more agitating scenes in the house and when her own state ceased to interest her aunt, who was entirely occupied with the dispute - that it should have been this period of accumulation and retention that left her the legacy of the mnemonic symbol.

I hope this girl, whose sexual sensibility had been injured at such an early age, derived some benefit from our conversation. I have not seen her since.

DISCUSSION

If someone were to assert that the present case history is not so much an analysed case of hysteria as a case solved by guessing, I should have nothing to say against him. It is true that the patient agreed that what I interpolated into her story was probably true; but she was not in a position to recognize it as something she had experienced. I believe it would have required hypnosis to bring that about. Assuming that my guesses were correct, I will now attempt to fit the case into the schematic picture of an 'acquired' hysteria on the lines suggested by Case 3. It seems plausible, then, to compare the two sets of erotic experiences with 'traumatic' moments and the scene of discovering the couple with an 'auxiliary' moment. The similarity lies in the fact that in the former experiences an element of consciousness was created which was excluded from the thought-activity of the ego and remained, as it were, in storage, while in the latter scene a new impression forcibly brought about an associative connection between this separated group and the ego. On the other hand there are dissimilarities which cannot be overlooked. The cause of the isolation was not, as in Case 3, an act of will on the part of the ego but *ignorance* on the part of the ego, which was not yet capable of coping with sexual experiences. In this respect the case of Katharina is typical. In every analysis of a case of hysteria based on sexual traumas we find that impressions from the pre-sexual period which produced no effect on the child attain traumatic power at a later date as memories, when the girl or married woman has acquired an understanding of sexual life. The splitting-off of psychical groups may be said to be a normal process in adolescent development; and it is easy to see that their later reception into the ego affords frequent opportunities for psychical disturbances. Moreover, I should like at this point to express a doubt as to whether a splitting of consciousness due to ignorance is really different from one due to conscious rejection, and whether even adolescents do not possess sexual knowledge far oftener than is supposed or than they themselves believe.

A further distinction in the psychical mechanism of this case lies in the fact that the scene of discovery, which we have described as 'auxiliary', deserves equally to be called 'traumatic'. It was operative on account of its own content and not merely as something that revived previous traumatic experiences. It combined the characteristics of an 'auxiliary' and a 'traumatic' moment. There seems no reason, however, why this coincidence should lead us to abandon a conceptual separation which in other cases corresponds also to a separation in time. Another peculiarity of Katharina's case, which, incidentally, has long been familiar to us, is seen in the circumstance that the conversion, the production of the hysterical phenomena, did not occur immediately after the trauma but after an interval of incubation. Charcot liked to describe this interval as the 'period of psychical working-out' [*élaboration*].

The anxiety from which Katharina suffered in her attacks was a hysterical one; that is, it was a reproduction of the anxiety which had appeared in connection with each of the sexual traumas. I shall not here comment on the fact which I have found regularly present in a very large number of cases - namely that a mere suspicion of sexual relations calls up the affect of anxiety in virginal individuals.¹

¹ (*Footnote added 1924:*) I venture after the lapse of so many years to lift the veil of discretion and reveal the fact that Katharina was not the niece but the daughter of the landlady. The girl fell ill, therefore, as a result of sexual attempts on the part of her own father. Distortions like the one which I introduced in the present instance should be altogether avoided in reporting a case history. From the point of view of understanding the case, a distortion of this kind is not, of course, a matter of such indifference as would be shifting the scene from one mountain to another.

CASE 5

FRÄULEIN ELISABETH VON R. (Freud)

In the autumn of 1892 I was asked by a doctor I knew to examine a young lady who had been suffering for more than two years from pains in her legs and who had difficulties in walking. When making this request he added that he thought the case was one of hysteria, though there was no trace of the usual indications of that neurosis. He told me that he knew the family slightly and that during the last few years it had met with many misfortunes and not much happiness. First the patient's father had died, then her mother had had to undergo a serious eye-operation and soon afterwards a married sister had succumbed to a heart-affection of long standing after a confinement. In all these troubles and in all the sick-nursing involved, the largest share had fallen to our patient.

My first interview with this young woman of twenty-four years of age did not help me to make much further progress in understanding the case. She seemed intelligent and mentally normal and bore her troubles, which interfered with her social life and pleasures, with a cheerful air - the *belle indifférence* of a hysteric, I could not help thinking. She walked with the upper part of her body bent forward, but without making use of any support. Her gait was not of any recognized pathological type, and moreover was by no means strikingly bad. All that was apparent was that she complained of great pain in walking and of being quickly overcome by fatigue both in walking and in standing, and that after a short time she had to rest, which lessened the pains but did not do away with them altogether. The pain was of an indefinite character; I gathered that it was something in the nature of a painful fatigue. A fairly large, ill defined area of the anterior surface of the right thigh was indicated as the focus of the pains, from which they most often radiated and where they reached their greatest intensity. In this area the skin and muscles were also particularly sensitive to pressure and pinching (though the prick of a needle was, if anything, met with a certain amount of unconcern). This hyperalgesia of the skin and muscles was not restricted to this area but could be observed more or less over the whole of both legs. The muscles were perhaps even more sensitive to pain than the skin; but there could be no question that the thighs were the parts most sensitive to both these kinds of pain. The motor power of the legs could not be described as small, and the reflexes were of medium strength. There were no other symptoms, so that there was no ground for suspecting the presence of any serious organic affection. The disorder had developed gradually during the previous two years and varied greatly in intensity.

I did not find it easy to arrive at a diagnosis, but I decided for two reasons to assent to the one proposed by my colleague, viz. that it was a case of hysteria. In the first place I was struck by the indefiniteness of all the descriptions of the character of her pains given me by the patient, who was nevertheless a highly intelligent person. A patient suffering from organic pains will, unless he is neurotic in addition, describe them definitely and calmly. He will say, for instance, that they are shooting pains, that they occur at certain intervals, that they extend from this place to that and that they seem to him to be brought on by one thing or another. Again, when a neurasthenic¹ describes his pains, he gives an impression of being engaged on a difficult intellectual task to which his strength is quite unequal. His features are strained and distorted as though under the influence of a distressing affect. His voice grows more shrill and he struggles to find a means of expression. He rejects any description of his pains proposed by the physician, even though it may turn out afterwards to have been unquestionably apt. He is clearly of opinion that language is too poor to find words for his sensations and that those sensations are something unique and previously unknown, of which it would be quite impossible to give an exhaustive description. For this reason he never tires of constantly adding fresh details, and when he is obliged to break off he is sure to be left with the conviction that he has not succeeded in making himself understood by the physician. All this is because his pains have attracted his whole attention to themselves. Fräulein von R. behaved in quite an opposite way; and we are driven to conclude that, since she nevertheless attached sufficient importance to her symptoms, her attention must be dwelling on something else, of which the pains were only an accessory phenomenon - probably on thoughts and feelings, therefore, which were connected with them.

¹ (A hypochondriac or a person affected with anxiety neurosis.)

But there is a second factor which is even more decisively in favour of this view of the pains. If one stimulates an area sensitive to pain in someone with an organic illness or in a neurasthenic, the patient's face takes on an expression of discomfort or physical pain. Moreover he flinches and draws back from the examination and resists it. In the case of Fräulein von R., however, if one pressed or pinched the hyperalgesic skin and muscles of her legs, her face assumed a peculiar expression, which was one of pleasure rather than pain. She cried out - and I could not help thinking that it was as though she was having a voluptuous tickling sensation - her face flushed, she threw back her head and shut her eyes and her body bent backwards. None of this was very exaggerated but it was distinctly noticeable, and it could only be reconciled with the view that her disorder was hysterical, and that the stimulation had touched upon a hysterogenic zone.

Her expression of face did not fit in with the pain which was ostensibly set up by the pinching of her muscles and skin; it was probably more in harmony with the subject-matter of the thoughts which lay concealed behind the pain and which had been aroused in her by the stimulation of the parts of the body associated with those thoughts. I had repeatedly observed expressions of similar significance in undoubted cases of hysteria, when a stimulus was applied to their hyperalgesic zones. Her other gestures were evidently very slight hints of a hysterical attack.

To begin with there was no explanation of the unusual localization of her hysterogenic zone. The fact that the hyperalgesia mainly affected the muscles also gave food for thought. The disorder which is most usually responsible for diffuse and local sensitivity to pressure in the muscles is a rheumatic infiltration of those muscles - common chronic muscular rheumatism. I have already spoken of its tendency to simulate nervous affections. This possibility was not contradicted by the consistency of the patient's hyperalgesic muscles. There were numerous hard fibres in the muscular substance, and these seemed especially sensitive. Thus it was probable that an organic change in the muscles of the kind indicated was present and that the neurosis attached itself to this and made it seem of exaggerated importance.

Treatment proceeded on the assumption that the disorder was of this mixed kind. We recommended the continuation of systematic kneading and faradization of the sensitive muscles, regardless of the resulting pain, and I reserved to myself treatment of her legs with high tension electric currents, in order to be able to keep in touch with her. Her question whether she should force herself to walk was answered with a decided 'yes'.

In this way we brought about a slight improvement. In particular, she seemed to take quite a liking to the painful shocks produced by the high tension apparatus, and the stronger these were the more they seemed to push her own pains into the background. In the meantime my colleague was preparing the ground for psychical treatment, and when, after four weeks of my pretence treatment, I proposed the other method and gave her some account of the procedure and mode of operation, I met with quick understanding and little resistance.

The task on which I now embarked turned out, however, to be one of the hardest that I had ever undertaken, and the difficulty of giving a report upon it is comparable, moreover, with the difficulties that I had then to overcome. For a long time, too, I was unable to grasp the connection between the events in her illness and her actual symptom, which must nevertheless have been caused and determined by that set of experiences.

When one starts upon a cathartic treatment of this kind, the first question one asks oneself is whether the patient herself is aware of the origin and the precipitating cause of her illness. If so, no special technique is required to enable her to reproduce the story of her illness. The interest shown in her by the physician, the understanding of her which he allows her to feel and the hopes of recovery he holds out to her - all these will decide the patient to yield up her secret. From the beginning it seemed to me probable that Fräulein Elisabeth was conscious of the basis of her illness, that what she had in her consciousness was only a secret and not a foreign body. Looking at her, one could not help thinking of the poet's words:

Das Mäskchen da weissagt verborgnen Sinn.¹

¹ ['Her mask reveals a hidden sense.'] Nevertheless, it will be seen later that I was mistaken in this.

In the first instance, therefore, I was able to do without hypnosis, with the reservation, however, that I could make use of it later if in the course of her confession material arose to the elucidation of which her memory was unequal. Thus it came about that in this, the first full-length analysis of a hysteria undertaken by me, I arrived at a procedure which I later developed into a regular method and employed deliberately. This procedure was one of clearing away the pathogenic psychical material layer by layer, and we liked to compare it with the technique of excavating a buried city. I would begin by getting the patient to tell me what was known to her and I would carefully note the points at which some train of thought remained obscure or some link in the causal chain seemed to be missing. And afterwards I would penetrate into deeper layers of her memories at these points by carrying out an investigation under hypnosis or by the use of some similar technique. The whole work was, of course, based on the expectation that it would be possible to establish a completely adequate set of determinants for the events concerned. I shall discuss presently the methods used for the deep investigation.

The story which Fräulein Elisabeth told of her illness was a wearisome one, made up of many different painful experiences. While she told it she was not under hypnosis; but I made her lie down and keep her eyes shut, though I made no objection to her occasionally opening them, changing her position, sitting up, and so on. When she was more deeply moved than usual by a part of her story she seemed to fall into a state more or less resembling hypnosis. She would then lie motionless and keep her eyes tightly shut.

I will begin by repeating what emerged as the most superficial layer of her memories. The youngest of three daughters, she was tenderly attached to her parents and spent her youth on their estate in Hungary. Her mother's health was frequently troubled by an affection of the eyes as well as by nervous states. Thus it came about that she found herself drawn into especially intimate contact with her father, a vivacious man of the world, who used to say that this daughter of his took the place of a son and a friend with whom he could exchange thoughts. Although the girl's mind found intellectual stimulation from this relationship with her father, he did not fail to observe that her mental constitution was on that account departing from the ideal which people like to see realized in a girl. He jokingly, called her 'cheeky' and 'cock-sure', and warned her against being too positive in her judgements and against her habit of regardlessly telling people the truth, and he often said she would find it hard to get a husband. She was in fact greatly discontented with being a girl. She was full of ambitious plans. She wanted to study or to have a musical training, and she was indignant at the idea of having to sacrifice her inclinations and her freedom of judgement by marriage. As it was, she nourished herself on her pride in her father and in the prestige and social position of her family, and she jealously guarded everything that was bound up with these advantages. The unselfishness, however, with which she put her mother and elder sisters first, when an occasion arose, reconciled her parents completely to the harsher side of her character.

In view of the girls' ages it was decided that the family should move to the capital, where Elisabeth was able for a short time to enjoy a fuller and gayer life in the home circle. Then, however, the blow fell which destroyed the happiness of the family. Her father had concealed, or had perhaps himself overlooked, a chronic affection of the heart, and he was brought home unconscious one day suffering from a pulmonary oedema. He was nursed for eighteen months, and Elisabeth saw to it that she played the leading part at his sick-bed. She slept in his room, was ready to wake if he called her at night, looked after him during the day and forced herself to appear cheerful, while he reconciled himself to his hopeless state with uncomplaining resignation. The beginning of her illness must have been connected with this period of nursing, for she remembered that during its last six months she had taken to her bed for a day and a half on account of the pains we have described. She asserted, however, that these pains quickly passed off and had not caused her any uneasiness or attracted her attention. And in fact it was not until two years after her father's death that she felt ill and became incapable of walking on account of her pains.

The gap that was caused in the life of this family of four women by her father's death, their social isolation, the breaking-off of so many connections that had promised to bring her interest and enjoyment, her mother's ill-health which was now becoming more marked - all this cast a shadow over the patient's state of feeling; but at the same time it kindled a lively desire in her that her family might soon find something to replace their lost happiness, and led her to concentrate her whole affection and care on the mother who was still living.

When the year of mourning had passed, her elder sister married a gifted and energetic man. He occupied a responsible position and his intellectual powers seemed to promise him a great future. But to his closer acquaintances he exhibited a morbid sensitiveness and an egoistic insistence on his fads; and he was the first in the family circle to venture to show lack of consideration for the old lady. This was more than Elisabeth could bear. She felt called upon to take up the fight against her brother-in-law whenever he gave her occasion, while the other women did not take his temperamental outbursts to heart. It was a painful disappointment to her that the rebuilding of their former family happiness should be thus interrupted; and she could not forgive her married sister for the feminine pliancy with which she persistently avoided taking sides. Elisabeth retained a number of scenes in her memory in this connection, involving complaints, in part not expressed in words, against her first brother-in-law. But her chief reproach against him remained the fact that, for the sake of a prospective promotion, he moved with his small family to a remote town in Austria and thus helped to increase her mother's isolation. On this occasion Elisabeth felt acutely her helplessness, her inability to afford her mother a substitute for the happiness she had lost and the impossibility of carrying out the intention she had formed at her father's death.

The marriage of her second sister seemed to promise a brighter future for the family, for the second brother-in-law, though less outstanding intellectually, was a man after the heart of these cultivated women, brought up as they had been in a school of consideration for others. His behaviour reconciled Elisabeth to the institution of marriage and to the thought of the sacrifices it involved. Moreover the second young couple remained in her mother's neighbourhood, and their child became Elisabeth's favourite. Unfortunately another event cast a shadow over the year in which this child was born. The treatment of her mother's eye-trouble necessitated her being kept in a dark room for several weeks, during which Elisabeth was with her. An operation was then pronounced unavoidable. The agitation at this prospect coincided with the preparations for her first brother-in-law's move. At last her mother came through the operation, which was performed by a master hand. The three families were united at a summer holiday resort, and it was hoped that Elisabeth, who had been exhausted by the anxieties of the last few months, would make a complete recovery during what was the first period of freedom from sorrows and fears that the family had enjoyed since her father's death.

It was precisely during this holiday, however, that Elisabeth's pains and locomotor weakness started. She had been to some extent aware of the pains for a short while, but they came on violently for the first time after she had had a warm bath in the bath establishment of the little watering-place. A few days earlier she had been for a long walk - in fact a regular tramp lasting half a day - and this they connected with the appearance of the pains, so that it was easy to take the view that Elisabeth had first been 'overtired' and had then 'caught a cold'.

From this time on Elisabeth was the invalid of the family. She was advised by her doctor to devote the rest of the same summer to a course of hydropathic treatment at Gastein, and she went there with her mother. But a fresh anxiety now arose. Her second sister had become pregnant again and reports of her condition were most unfavourable, so that Elisabeth could hardly make up her mind to travel to Gastein. She and her mother had been there for barely a fortnight when they were called back by the news that her sister, who had now taken to her bed, was in a very bad state.

There followed an agonizing journey, during which Elisabeth was tormented not only by her pains but by dreadful expectations; on their arrival at the station there were signs that led them to fear the worst; and when they entered the sick-room there came the certainty that they had come too late to take their leave of a living person.

Elisabeth suffered not only from the loss of this sister, whom she had dearly loved, but almost as much from the thoughts provoked by her death and the changes which it brought along with it. Her sister had succumbed to an affection of the heart which had been aggravated by her pregnancy. The idea now presented itself that heart disease was inherited from the father's side of the family. It was then recalled that the dead sister had suffered during her early girlhood from chorea accompanied by a mild cardiac disorder. They blamed themselves and the doctors for having permitted the marriage, and it was impossible to spare the unhappy widower the reproach of having endangered his wife's health by bringing on two pregnancies in immediate succession. From that time onwards Elisabeth's thoughts were occupied without interruption with the gloomy reflection that when, for once in a way, the rare conditions for a happy marriage had been fulfilled, this happiness should have come to such an end. Furthermore, she saw the collapse once more of all she had desired for her mother. Her widowed brother-in-law was inconsolable and withdrew from his wife's family. It appeared that his own family, which had been estranged from him during his short, happy marriage, thought this was a favourable moment for drawing him back into their own circle. There was no way of preserving the unity that had existed formerly. It was not practicable for him to live with her mother in view of Elisabeth's unmarried state. Since, also, he refused to allow the two women to have the custody of the child, which was the dead woman's only legacy, he gave them occasion for the first time to accuse him of hard-heartedness. Lastly - and this was not the least distressing fact - a rumour reached Elisabeth that a dispute had arisen between her two brothers-in-law. She could only guess at its cause; it seemed, however, that the widower had put forward financial demands which the other declared were unjustifiable and which, indeed, in view of the mother's present sorrow, he was able to characterize as blackmail of the worst description.

Here, then, was the unhappy story of this proud girl with her longing for love. Unreconciled to her fate, embittered by the failure of all her little schemes for re-establishing the family's former glories, with those she loved dead or gone away or estranged, unready to take refuge in the love of some unknown man - she had lived for eighteen months in almost complete seclusion, with nothing to occupy her but the care of her mother and her own pains.

If we put greater misfortunes on one side and enter into a girl's feelings, we cannot refrain from deep human sympathy with Fräulein Elisabeth. But what shall we say of the purely medical interest of this tale of suffering, of its relations to her painful locomotor weakness, and of the chances of an explanation and cure afforded by our knowledge of these psychical traumas?

As far as the physician was concerned, the patient's confession was at first sight a great disappointment. It was a case history made up of commonplace emotional upheavals, and there was nothing about it to explain why it was particularly from hysteria that she fell ill or why her hysteria took the particular form of a painful abasia. It threw light neither on the causes nor the specific determination of her hysteria. We might perhaps suppose that the patient had formed an association between her painful mental impressions and the bodily pains which she happened to be experiencing at the same time, and that now, in her life of memories, she was using her physical feelings as a symbol of her mental ones. But it remained unexplained what her motives might have been for making a substitution of this kind and at what moment it had taken place. These, incidentally, were not the kind of questions that physicians were in the habit of raising. We were usually content with the statement that the patient was constitutionally a hysteric, liable to develop hysterical symptoms under the pressure of intense excitations *of whatever kind*.

Her confession seemed to offer even less help towards the cure of her illness than it did towards its explanation. It was not easy to see what beneficent influence Fräulein Elisabeth could derive from recapitulating the tale of her sufferings of recent years - with which all the members of her family were so familiar - to a stranger who received it with only a moderate sympathy. Nor was there any sign of the confession producing a curative effect of this kind. During this first period of her treatment she never failed to repeat that she was still feeling ill and that her pains were as bad as ever; and, when she looked at me as she said this with a sly look of satisfaction at my discomfort, I could not help being reminded of old Herr von R.'s judgement about his favourite daughter - that she was often 'cheeky' and 'ill-behaved'. But I was obliged to admit that she was in the right.

If I had stopped the patient's psychical treatment at this stage, the case of Fräulein Elisabeth von R. would clearly have thrown no light on the theory of hysteria. But I continued my analysis because I firmly expected that deeper levels of her consciousness would yield an understanding both of the causes and the specific determinants of the hysterical symptoms. I therefore decided to put a direct question to the patient in an enlarged state of consciousness and to ask her what psychical impression it had been to which the first emergence of pains in her legs had been attached.

With this end in view I proposed to put the patient into a deep hypnosis. But, unfortunately, I could not help observing that my procedure failed to put her into any state other than the one in which she had made her recital. I was glad enough that on this occasion she refrained from triumphantly protesting: 'I'm not asleep, you know; I can't be hypnotized.' In this extremity the idea occurred to me of resorting to the device of applying pressure to the head, the origin of which I have described in full in the case history of Miss Lucy. I carried this out by instructing the patient to report to me faithfully whatever appeared before her inner eye or passed through her memory at the moment of the pressure. She remained silent for a long time and then, on my insistence, admitted that she had thought of an evening on which a young man had seen her home after a party, of the conversation that had taken place between them and of the feelings with which she had returned home to her father's sick-bed.

This first mention of the young man opened up a new vein of ideas the contents of which I now gradually extracted. It was a question here of a secret, for she had initiated no one, apart from a common friend, into her relations with the young man and the hopes attached to them. He was the son of a family with which they had long been on friendly terms and who lived near their former estate. The young man, who was himself an orphan, was devotedly attached to her father and followed his advice in pursuing his career. He had extended his admiration for her father to the ladies of the family. Numerous recollections of reading together, of exchanging ideas, and of remarks made by him which were repeated to her by other people, bore witness to the gradual growth in her of a conviction that he loved her and understood her and that marriage with him would not involve the sacrifices on her part which she dreaded from marriage in general. Unluckily, he was scarcely any older than herself and was still far from being self-supporting. But she was firmly determined to wait for him.

After her father had fallen seriously ill and she had been so much taken up with looking after him, her meetings with her friend became more and more rare. The evening which she had first remembered represented what had actually been the climax of her feeling; but even then there had been no *éclaircissement* between them. On that occasion she had allowed herself to be persuaded, by the insistence of her family and of her father himself, to go to a party at which she was likely to meet him. She had wanted to hurry home early but had been pressed to stay and had given way when he promised to see her home. She had never had such warm feelings towards him as while he was accompanying her that evening. But when she arrived home late in this blissful frame of mind, she found her father was worse and reproached herself most bitterly for having sacrificed so much time to her own enjoyment. This was the last time she left her sick father for a whole evening. She seldom met her friend after this. After her father's death the young man seemed to keep away from her out of respect for her sorrow. The course of his life then took him in other directions. She had to familiarize herself by degrees with the thought that his interest in her had been displaced by others and that she had lost him. But this disappointment in her first love still hurt her whenever she thought of him.

It was therefore in this relationship and in the scene described above in which it culminated that I could look for the causes of her first hysterical pains. The contrast between the blissful feelings she had allowed herself to enjoy on that occasion and the worsening of her father's state which had met her on her return home constituted a conflict, a situation of incompatibility. The outcome of this conflict was that the erotic idea was repressed from association and the affect attaching to that idea was used to intensify or revive a physical pain which was present simultaneously or shortly before. Thus it was an instance of the mechanism of conversion for the purpose of defence, which I have described in detail elsewhere.

A number of comments might of course be made at this point. I must emphasize the fact that I did not succeed in establishing from her memory that the conversion took place at the moment of her return home. I therefore looked about for similar experiences during the time she was nursing her father and elicited a number of them. Among these, special prominence attached, on account of their frequent occurrence, to scenes in which, at her father's call, she had jumped out of bed with bare feet in a cold room. I was inclined to attribute some importance to these factors, since in addition to complaining about the pain in her legs she also complained of tormenting sensations of cold. Nevertheless, even here I was unable to get hold of any scene which it was possible to identify as that at which the conversion had occurred. I was inclined for this reason to think that there was a gap in the explanation at this point, until I recollected that the hysterical pains in the legs had in fact not made their appearance during the period when she was nursing her father. She only remembered a single attack of pain, which had only lasted a day or two and had not attracted her attention. I now directed my enquiries to this first appearance of the pains. I succeeded in reviving the patient's memory of it with certainty. At that very time a relative had visited them and she had been unable to receive him, owing to being laid up in bed. This same man had been unlucky enough, when he visited them again two years later, to find her in bed once more. But in spite of repeated attempts we failed to trace any psychical cause for the first pains. I thought it safe to assume that they had in fact appeared without any psychical cause and were a mild rheumatic affection; and I was able to establish that this organic disorder, which was the model copied in her later hysteria, had in any case to be dated before the scene of her being accompanied back from the party. From the nature of things it is nevertheless possible that these pains, being of organic origin, may have persisted for some time to a mitigated degree without being very noticeable. The obscurity due to the fact that the analysis pointed to the occurrence of a conversion of psychical excitation into physical pain though that pain was certainly not perceived at the time in question or remembered afterwards - this is a problem which I hope to be able to solve later on the basis of further considerations and later examples.¹

¹ I cannot exclude the possibility, though I cannot establish the fact, that these pains, which chiefly affected the thighs, were of a *neurasthenic* nature.

The discovery of the reason for the first conversion opened a second, fruitful period of the treatment. The patient surprised me soon afterwards by announcing that she now knew why it was that the pains always radiated from that particular area of the right thigh and were at their most painful there: it was in this place that her father used to rest his leg every morning, while she renewed the bandage round it, for it was badly swollen. This must have happened a good hundred times, yet she had not noticed the connection till now. In this way she gave me the explanation that I needed of the emergence of what was an atypical hysterogenic zone. Further, her painful legs began to 'join in the conversation' during our analyses. What I have in mind is the following remarkable fact. As a rule the patient was free from pain when we started work. If, then, by a question or by pressure upon her head I called up a memory, a sensation of pain would make its first appearance, and this was usually so sharp that the patient would give a start and put her hand to the painful spot. The pain that was thus aroused would persist so long as she was under the influence of the memory; it would reach its climax when she was in the act of telling me the essential and decisive part of what she had to communicate, and with the last word of this it would disappear. I came in time to use such pains as a compass to guide me; if she stopped talking but admitted that she still had a pain, I knew that she had not told me everything, and insisted on her continuing her story till the pain had been talked away. Not until then did I arouse a fresh memory.

During this period of 'abreaction' the patient's condition, both physical and mental, made such a striking improvement that I used to say, only half jokingly, that I was taking away a certain amount of her motives for pain every time and that when I had cleared them all away she would be well. She soon got to the point of being without pain most of the time; she allowed herself to be persuaded to walk about a great deal and to give up her former isolation. In the course of the analysis I sometimes followed the spontaneous fluctuations in her condition; and I sometimes followed my own estimate of the situation when I considered that I had not completely exhausted some portion of the story of her illness.

During this work I made some interesting observations, whose lessons I subsequently found confirmed in treating other patients. As regards the spontaneous fluctuations, in the first place, I found that in fact none had occurred which had not been provoked by association with some contemporary event. On one occasion she had heard of an illness of one of her acquaintances which reminded her of a detail of her father's illness; another time her dead sister's child had been on a visit to them, and its likeness to its mother had stirred up her feelings of grief; and yet another time a letter from her distant sister showed clear evidence of her unfeeling brother-in-law's influence and gave rise to a pain which required her to produce the story of a family scene which she had not yet told me about. Since she never brought up the same precipitating cause of a pain twice over, it seemed that we were justified in supposing that we should in this way exhaust the stock of them; and I therefore did not hesitate to get her into situations which were calculated to bring up fresh memories which had not yet reached the surface. For instance, I sent her to visit her sister's grave, and I encouraged her to go to a party at which she might once more come across the friend of her youth.

In the next place, I obtained some insight into the manner of origin of what might be described as a 'monosymptomatic' hysteria. For I found that her *right* leg became painful under hypnosis when the discussion turned on her nursing her sick father, on her relations with the friend of her youth or on other events falling within the first period of her pathogenic experiences; on the other hand, the pain made its appearance in her other, *left*, leg as soon as I stirred up a memory relating to her dead sister or her two brothers-in-law - in short, to an impression from the second half of the story of her illness. Having thus had my attention aroused by the regularity of this relation, I carried my investigation further and formed an impression that this differentiation went still further and that every fresh psychical determinant of painful sensations had become attached to some fresh spot in the painful area of her legs. The original painful spot in her right thigh had related to her nursing her father; the area of pain had extended from this spot to neighbouring regions as a result of fresh traumas. Here, therefore, what we were dealing with was not strictly speaking a *single* physical symptom, linked with a variety of mnemonic complexes in the mind, but a number of similar symptoms which appeared, on a superficial view, to be merged into one symptom. But I did not pursue further the delimitation of zones of pain corresponding to different psychical determinants, since I found that the patient's attention was directed away from this subject.

I did, however, turn my attention to the way in which the whole symptomatic complex of abasia might have been built up upon these painful zones, and in that connection I asked her various questions, such as what was the origin of her pains in walking? in standing? and in lying down? Some of these questions she answered spontaneously, some under the pressure of my hand. Two things emerged from this. In the first place she divided all the scenes with painful impressions attached to them into groups for me, according as she had experienced them while she was sitting or standing, and so on. For instance, she was *standing* by a door when her father was brought home with his heart attack, and in her fright she stood stock still as though she was rooted to the ground. She went on to add a number of other memories to this first example of fright while she was standing, till she came to the fearful scene in which once again she *stood*, as though spellbound, by her sister's death-bed. This whole chain of memories might be expected to show that there was a legitimate connection between her pains and standing up; and it might indeed be accepted as evidence of an association. But we must bear in mind that another factor must be proved to be present in all these events, one which directed her attention precisely to her standing (or, as the case may be, to her walking, sitting, etc.) and consequently led to conversion. The explanation of her attention taking this direction can scarcely be looked for elsewhere than in the circumstance that walking, standing and lying are functions and states of those parts of her body which in her case comprised the painful zones, namely, her legs. It was therefore easy in the present case to understand the connection between the astasia-abasia and the first occurrence of conversion.

Among the episodes which, according to this catalogue, seemed to have made *walking* painful, one received special prominence: a walk which she had taken at the health resort in the company of a number of other people and which was supposed to have been too long. The details of this episode only emerged with hesitation and left several riddles unsolved. She had been in a particularly yielding mood, and eagerly joined her party of friends. It was a fine day, not too hot. Her mother stopped at home and her elder sister had already gone away. Her younger sister felt unwell, but did not want to spoil her enjoyment; the brother-in-law began by saying that he would stay with his wife, but afterwards decided to join the party on Elisabeth's account. This scene seemed to have had a great deal to do with the first appearance of the pains, for she remembered being very tired and suffering from violent pain when she returned from the walk. She said, however, that she was not certain whether she had already noticed the pains before this. I pointed out to her that she was unlikely to have undertaken such a long walk if she had had any considerable pains. I asked her what it was in the walk that might have brought on the pain and she gave me the somewhat obscure reply that the contrast between her own loneliness and her sick sister's married happiness (which her brother-in-law's behaviour kept constantly before her eyes) had been painful to her.

Another scene, which was very close to the former one in time, played a part in linking the pains with *sitting*. It was a few days later. Her sister and brother-in-law had already left the place. She found herself in a restless, yearning mood. She rose early in the morning and climbed a small hill to a spot which they had often been to together and which afforded a lovely view. She sat down there on a stone bench and gave herself up to her thoughts. These were once again concerned with her loneliness and the fate of her family; and this time she openly confessed to a burning wish that she might be as happy as her sister. She returned from this morning meditation with violent pains, and that same evening had the bath after which the pains made their final and permanent appearance.

It was further shown without any doubt that her pain in walking and standing used, to begin with, to be allayed when she was *lying down*. The pains were not linked to lying down as well until, after hearing the news of her sister's illness, she travelled back from Gastein and was tormented during the night alike by worry about her sister and by raging pains, as she lay, sleepless, stretched out in the railway carriage. And for quite a time after this, lying down was actually more painful to her than walking or standing.

In this way, firstly, the painful region had been extended by the addition of adjacent areas: every fresh theme which had a pathogenic effect had cathected a new region in the legs; secondly, each of the scenes which made a powerful impression on her had left a trace behind it, bringing about lasting and constantly accumulating cathexis of the various functions of the legs, a linking of these functions with her feelings of pain. But a third mechanism had unmistakably been involved in the building up of her astasia-abasia. The patient ended her description of a whole series of episodes by complaining that they had made the fact of her 'standing alone' painful to her. In another series of episodes, which comprised her unsuccessful attempts to establish a new life for her family, she was never tired of repeating that what was painful about them had been her feeling of helplessness, the feeling that she could not 'take a single step forward'. In view of this, I was forced to suppose that among the influences that went to the building up of her abasia, these reflections of hers played a part; I could not help thinking that the patient had done nothing more nor less than look for a *symbolic* expression of her painful thoughts and that she had found it in the intensification of her sufferings. The fact that somatic symptoms of hysteria can be brought about by symbolization of this kind was already asserted in our 'Preliminary Communication'. In the Discussion on the present case I shall bring forward two or three conclusive instances of this. This psychical mechanism of symbolization did not play a prominent part with Fräulein Elisabeth von R. It did not *create* her abasia. But everything goes to show that the abasia which was already present received considerable reinforcement in this way. Accordingly, this abasia, at the stage of development at which I came across it, was to be equated not only with a functional paralysis based on psychical associations but also with one based on symbolization.

Before I resume my account of the case I will add a few words on the patient's behaviour during this second phase of the treatment. Throughout the analysis I made use of the technique of bringing out pictures and ideas by means of pressing on the patient's head, a method, that is, which would be unworkable without the patient's full co-operation and willing attention. Sometimes, indeed, her behaviour fulfilled my highest expectations, and during such periods it was surprising with what promptitude the different scenes relating to a given theme emerged in a strictly chronological order. It was as though she were reading a lengthy book of pictures, whose pages were being turned over before her eyes. At other times there seemed to be impediments of whose nature I had no suspicion then. When I pressed her head she would maintain that nothing occurred to her. I would repeat my pressure and tell her to wait, but still nothing appeared. The first few times when this recalcitrance exhibited itself I allowed myself to be led into breaking off the work: it was an unfavourable day; we would try another time. Two observations, however, decided me to alter my attitude. I noticed, in the first place, that the method failed in this way only when I found Elisabeth in a cheerful state and free from pain, never when she was feeling badly. In the second place, that she often made such assertions as that she saw nothing, after she had allowed a long interval to pass during which her tense and preoccupied expression of face nevertheless betrayed the fact that a mental process was taking place in her. I resolved, therefore, to adopt the hypothesis that the procedure never failed: that on every occasion under the pressure of my hand some idea occurred to Elisabeth or some picture came before her eyes, but that she was not always prepared to communicate it to me, and tried to suppress once more what had been conjured up. I could think of two motives for this concealment. Either she was applying criticism to the idea, which she had no right to do, on the ground of its not being important enough or of its being an irrelevant reply to the question she had been asked; or she hesitated to produce it because she found it too disagreeable to tell. I therefore proceeded as though I was completely convinced of the trustworthiness of my technique. I no longer accepted her declaration that nothing had occurred to her, but assured her that something *must* have occurred to her. Perhaps, I said, she had not been sufficiently attentive, in which case I should be glad to repeat my pressure. Or perhaps she thought that her idea was not the right one. This, I told her, was not her affair; she was under an obligation to remain completely objective and say what had come into her head, whether it was appropriate or not. Finally I declared that I knew very well that something *had* occurred to her and that she was concealing it from me; but she would never be free of her pains so long as she concealed anything. By thus insisting, I brought it about that from that time forward my pressure on her head never failed in its effect. I could not but conclude that I had formed a correct opinion of the state of affairs, and I derived from this analysis a literally unqualified reliance on my technique. It often happened that it was not until I had pressed her head three times that she produced a piece of information; but she herself would remark afterwards: 'I could have said it to you the first time.' - 'And why didn't you?' - 'I thought it wasn't what was wanted', or 'I thought I could avoid it, but it came back each time.' In the course of this difficult work I began to attach a deeper significance to the resistance offered by the patient in the reproduction of her memories and to make a careful collection of the occasions on which it was particularly marked.

I have now arrived at the third period of the treatment. The patient was better. She had been mentally relieved and was now capable of successful effort. But her pains had manifestly, not been removed; they recurred from time to time, and with all their old severity. This incomplete therapeutic result corresponded to an incompleteness in the analysis. I still did not know exactly at what moment and by what mechanism the pains had originated. During the reproduction of the great variety of scenes in the second period and while I was observing the patient's resistance to telling me about them, I had formed a particular suspicion. I did not venture yet, however, to adopt it as the basis of my further action. But a chance occurrence decided the matter. One day while I was working with the patient, I heard a man's footsteps in the next room and a pleasant voice which seemed to be asking some question. My patient thereupon got up and asked that we might break off for the day: she had heard her brother-in-law arrive and enquire for her. Up to that point she had been free from pain, but after the interruption her facial expression and gait betrayed the sudden emergence of severe pains. My suspicion was strengthened by this and I determined to precipitate the decisive explanation.

I therefore questioned her about the causes and circumstances of the first appearance of the pains. By way of answer her thoughts turned towards her summer visit to the health resort before her journey to Gastein, and a number of scenes turned up once more which had not been treated very completely. She recalled her state of feeling at the time, her exhaustion after her anxieties about her mother's eyesight and after having nursed her at the time of her operation, and her final despair of a lonely girl like her being able to get any enjoyment out of life or achieve anything in it. Till then she had thought herself strong enough to be able to do without the help of a man; but she was now overcome by a sense of her weakness as a woman and by a longing for love in which, to quote her own words, her frozen nature began to melt. In this mood she was deeply affected by her second sister's happy marriage - by seeing with what touching care he looked after her, how they understood each other at a single glance and how sure they seemed to be of each other. It was no doubt to be regretted that the second pregnancy followed so soon after the first, and her sister knew that this was the reason of her illness; but how willingly she bore it because he was its cause. On the occasion of the walk which was so intimately connected with Elisabeth's pains, her brother-in-law had at first been unwilling to join in it and had wanted to stay by his sick wife. She, however, persuaded him with a look to go with them, because she thought it would give Elisabeth pleasure. Elisabeth remained in his company all through the walk. They discussed every kind of subject, among them the most intimate ones. She found herself in complete agreement with everything he said, and a desire to have a husband like him became very strong in her. Then, a few days later, came the scene on the morning after the departure of her sister and brother-in-law when she made her way to the place with a view, which had been a favourite object of their walks. There she sat down and dreamt once again of enjoying such happiness as her sister's and of finding a husband who would know how to capture her heart like this brother-in-law of hers. She was in pain when she stood up, but it passed off once more. It was not until the afternoon, when she had had the warm bath, that the pains broke out, and she was never again free from them. I tried to discover what thoughts were occupying her mind while she was having the bath; but I learnt only that the bath-house had reminded her of the members of her family who had gone away, because that was the building in which they had stayed.

It had inevitably become clear to me long since what all this was about; but the patient, deep in her bitter-sweet memories, seemed not to notice the end to which she was steering, and continued to reproduce her recollections. She went on to her visit to Gastein, the anxiety with which she looked forward to every letter, finally the bad news about her sister, the long wait till the evening, which was the first moment at which they could get away from Gastein, then the journey, passed in tormenting uncertainty, and the sleepless night - all of these accompanied by a violent increase in her pains. I asked her whether during the journey she had thought of the grievous possibility which was afterwards realized. She answered that she had carefully avoided the thought, but she believed that her mother had from the beginning expected the worst. - Her memories now went on to their arrival in Vienna, the impression made on them by the relatives who met them, the short journey from Vienna to the summer resort in its neighbourhood where her sister lived, their reaching there in the evening, the hurried walk through the garden to the door of the small garden house, the silence within and the oppressive darkness; how her brother-in-law was not there to receive them, and how they stood before the bed and looked at her sister as she lay there dead. At that moment of dreadful certainty that her beloved sister was dead without bidding them farewell and without her having eased her last days with her care - at that very moment another thought had shot through Elisabeth's mind, and now forced itself irresistibly upon her once more, like a flash of lightning in the dark: 'Now he is free again and I can be his wife.'

Everything was now clear. The analyst's labours were richly rewarded. The concepts of the 'fending off' of an incompatible idea, of the genesis of hysterical symptoms through the conversion of psychical excitations into something physical and the formation of a separate psychical group through the act of will which led to the fending-off - all these things were, in that moment, brought before my eyes in concrete form. Thus and in no other way had things come about in the present case. This girl felt towards her brother-in-law a tenderness whose acceptance into consciousness was resisted by her whole moral being. She succeeded in sparing herself the painful conviction that she loved her sister's husband, by inducing physical pains in herself instead; and it was in the moments when this conviction sought to force itself upon her (on her walk with him, during her morning reverie, in the bath, by her sister's bedside) that her pains had come on, thanks to successful conversion. At the time when I started her treatment the group of ideas relating to her love had already been separated from her knowledge. Otherwise she would never, I think, have agreed to embarking on the treatment. The resistance with which she had repeatedly met the reproduction of scenes which operated traumatically corresponded in fact to the energy with which the incompatible idea had been forced out of her associations.

The period that followed, however, was a hard one for the physician. The recovery of this repressed idea had a shattering effect on the poor girl. She cried aloud when I put the situation drily before her with the words: 'So for a long time you had been in love with your brother-in-law.' She complained at this moment of the most frightful pains, and made one last desperate effort to reject the explanation: it was not true, I had talked her into it, it *could* not be true, she was incapable of such wickedness, she could never forgive herself for it. It was easy to prove to her that what she herself had told me admitted of no other interpretation. But it was a long time before my two pieces of consolation - that we are not responsible for our feelings, and that her behaviour, the fact that she had fallen ill in these circumstances, was sufficient evidence of her moral character - it was a long time before these consolations of mine made any impression on her.

In order to mitigate the patient's sufferings I had now to proceed along more than one path. In the first place I wanted to give her an opportunity of getting rid of the excitation that had been piling up so long, by 'abreacting' it. We probed into the first impressions made on her in her relations with her brother-in-law, the beginning of the feelings for him which she had kept unconscious. Here we came across all the little premonitory signs and intuitions of which a fully-grown passion can make so much in retrospect. On his first visit to the house he had taken her for the girl he was to marry and had greeted her before her elder but somewhat insignificant-looking sister. One evening they were carrying on such a lively conversation together and seemed to be getting on so well that his fiancée had interrupted them half-seriously with the remark: 'The truth is, you two would have suited each other splendidly.' Another time, at a party where they knew nothing of his engagement, the young man was being discussed and a lady criticized a defect in his figure which suggested that he had had a disease of the bones in his childhood. His fiancée herself listened quietly, but Elisabeth flared up and defended the symmetry of her future brother-in-law's figure with a zeal which she herself could not understand. As we worked through these recollections it became clear to Elisabeth that her tender feeling for her brother-in-law had been dormant in her for a long time, perhaps even from the beginning of her acquaintance with him, and had lain concealed all that time behind the mask of mere sisterly affection, which her highly-developed family feeling could enable her to accept as natural.

This process of abreaction certainly did her much good. But I was able to relieve her still more by taking a friendly interest in her present circumstances. With this end in view I arranged for an interview with Frau von R. I found her an understanding and sensitive lady, though her vital spirits had been reduced by her recent misfortunes. I learned from her that on closer examination the charge of unfeeling blackmail which had been brought by the elder brother-in-law against the widower and which had been so painful to Elisabeth had had to be withdrawn. No stain was left on the young man's character. It was a misunderstanding due to the different value which, as can readily be seen, would be attached to money by a business man, to whom money is a tool of his trade, and a civil servant. Nothing more than this remained of the painful episode. I begged her mother from that time forward to tell Elisabeth everything she needed to know, and in the future to give her the opportunity for unburdening her mind to which I should have accustomed her.

I was also, of course, anxious to learn what chance there was that the girl's wish, of which she was now conscious, would come true. Here the prospects were less favourable. Her mother told me that she had long ago guessed Elisabeth's fondness for the young man, though she had not known that the feeling had already been there during her sister's lifetime. No one seeing the two of them together - though in fact this had now become a rare event - could doubt the girl's anxiety to please him. But, she told me, neither she (the mother) nor the family advisers were particularly in favour of a marriage. The young man's health was by no means good and had received a fresh set-back from the death of his beloved wife. It was not at all certain, either, that his mental state was yet sufficiently recovered for him to contract a new marriage. This was perhaps why he was behaving with so much reserve; perhaps, too, it was because he was uncertain of his reception and wished to avoid comments that were likely to be made. In view of these reservations on both sides, the solution for which Elisabeth longed was unlikely to be achieved.

I told the girl what I had heard from her mother and had the satisfaction of benefiting her by giving her the explanation of the money affair. On the other hand I encouraged her to face with calmness the uncertainty about the future which it was impossible to clear up. But at this point the approach of summer made it urgent for us to bring the analysis to an end. Her condition was once more improved and there had been no more talk of her pains since we had been investigating their causes. We both had a feeling that we had come to a finish, though I told myself that the abreaction of the love she had so long kept down had not been carried out very fully. I regarded her as cured and pointed out to her that the solution of her difficulties would proceed on its own account now that the path had been opened to it. This she did not dispute. She left Vienna with her mother to meet her eldest sister and her family and to spend the summer together.

I have a few words to add upon the further course of Fräulein Elisabeth von R. 's case. Some weeks after we had separated I received a despairing letter from her mother. At her first attempt, she told me, to discuss her daughter's affairs of the heart with her, the girl had rebelled violently and had since then suffered from severe pains once more. She was indignant with me for having betrayed her secret. She was entirely inaccessible, and the treatment had been a complete failure. What was to be done now? she asked. Elisabeth would have nothing more to do with me. I did not reply to this. It stood to reason that Elisabeth after leaving my care would make one more attempt to reject her mother's intervention and once more take refuge in isolation. But I had a kind of conviction that everything would come right and that the trouble I had taken had not been in vain. Two months later they were back in Vienna, and the colleague to whom I owed the introduction of the case gave me news that Elisabeth felt perfectly well and was behaving as though there was nothing wrong with her, though she still suffered occasionally from slight pains. Several times since then she has sent me similar messages and each time promised to come and see me. But it is a characteristic of the personal relationship which arises in treatments of this kind that she has never done so. As my colleague assures me, she is to be regarded as cured. Her brother-in-law's connection with the family has remained unaltered.

In the spring of 1894 I heard that she was going to a private ball for which I was able to get an invitation, and I did not allow the opportunity to escape me of seeing my former patient whirl past in a lively dance. Since then, by her own inclination, she has married someone unknown to me.

DISCUSSION

I have not always been a psychotherapist. Like other neuropathologists, I was trained to employ local diagnoses and electro-prognosis, and it still strikes me myself as strange that the case histories I write should read like short stories and that, as one might say, they lack the serious stamp of science. I must console myself with the reflection that the nature of the subject is evidently responsible for this, rather than any preference of my own. The fact is that local diagnosis and electrical reactions lead nowhere in the study of hysteria, whereas a detailed description of mental processes such as we are accustomed to find in the works of imaginative writers enables me, with the use of a few psychological formulas, to obtain at least some kind of insight into the course of that affection. Case histories of this kind are intended to be judged like psychiatric ones; they have, however, one advantage over the latter, namely an intimate connection between the story of the patient's sufferings and the symptoms of his illness - a connection for which we still search in vain in the biographies of other psychoses.

In reporting the case of Fräulein Elisabeth von R. I have endeavoured to weave the explanations which I have been able to give of the case into my description of the course of her recovery. It may perhaps be worth while to bring together the important points once more. I have described the patient's character, the features which one meets with so frequently in hysterical people and which there is no excuse for regarding as a consequence of degeneracy: her giftedness, her ambition, her moral sensibility, her excessive demand for love which, to begin with, found satisfaction in her family, and the independence of her nature which went beyond the feminine ideal and found expression in a considerable amount of obstinacy, pugnacity and reserve. No appreciable hereditary taint, so my colleague told me, could be traced on either side of her family. It is true that her mother suffered for many years from a neurotic depression which had not been investigated; but her mother's brothers and sisters and her father and his family could be regarded as well-balanced people free from nervous trouble. No severe case of neuro-psychosis had occurred among her close relatives.

Such was the patient's nature, which was now assailed by painful emotions, beginning with the lowering effect of nursing her beloved father through a long illness.

There are good reasons for the fact that sick-nursing plays such a significant part in the prehistory of cases of hysteria. A number of the factors at work in this are obvious: the disturbance of one's physical health arising from interrupted sleep, the neglect of one's own person, the effect of constant worry on one's vegetative functions. But, in my view, the most important determinant is to be looked for elsewhere. Anyone whose mind is taken up by the hundred and one tasks of sick-nursing which follow one another in endless succession over a period of weeks and months will, on the one hand, adopt a habit of suppressing every sign of his own emotion, and on the other, will soon divert his attention away from his own impressions, since he has neither time nor strength to do justice to them. Thus he will accumulate a mass of impressions which are capable of affect, which are hardly sufficiently perceived and which, in any case, have not been weakened by abreaction. He is creating material for a 'retention hysteria'. If the sick person recovers, all these impressions, of course, lose their significance. But if he dies, and the period of mourning sets in, during which the only things that seem to have value are those that relate to the person who has died, these impressions that have not yet been dealt with come into the picture as well; and after a short interval of exhaustion the hysteria, whose seeds were sown during the time of nursing, breaks out.

We also occasionally come across this same fact of the traumas accumulated during sick-nursing being dealt with subsequently, where we get no general impression of illness but where the mechanism of hysteria is nevertheless retained. Thus I am acquainted with a highly-gifted lady who suffers from slight nervous states and whose whole character bears evidence of hysteria, though she has never had to seek medical help or been unable to carry on her duties. She has already nursed to the end three or four of those whom she loved. Each time she reached a state of complete exhaustion; but she did not fall ill after these tragic efforts. Shortly after her patient's death, however, there would begin in her a work of reproduction which once more brought up before her eyes the scenes of the illness and death. Every day she would go through each impression once more, would weep over it and console herself - at her leisure, one might say. This process of dealing with her impressions was dovetailed into her everyday tasks without the two activities interfering with each other. The whole thing would pass through her mind in chronological sequence. I cannot say whether the work of recollection corresponded day by day with the past. I suspect that this depended on the amount of leisure which her current household duties allowed.

In addition to these outbursts of weeping with which she made up arrears and which followed close upon the fatal termination of the illness, this lady celebrated annual festivals of remembrance at the period of her various catastrophes, and on these occasions her vivid visual reproduction and expression of feeling kept to the date precisely. For instance, on one occasion I found her in tears and asked her sympathetically what had happened that day. She brushed aside my question half-angrily: 'Oh no,' she said, 'it is only that the specialist was here again to-day and gave us to understand that there was no hope. I had no time to cry about it then.' She was referring to the last illness of her husband, who had died three years earlier. I should be very much interested to know whether the scenes which she celebrated at these annual festivals of remembrance were always the same ones or whether different details presented themselves for abreaction each time, as I suspect in view of my theory.¹ But I cannot discover with certainty. The lady, who had no less strength of character than intelligence, was ashamed of the violent effect produced in her by these reminiscences.

I must emphasize once more: this woman is not ill; her postponed abreaction was not a hysterical process, however much it resembled one. We may ask why it should be that one instance of sick-nursing should be followed by a hysteria and another not. It cannot be a matter of individual predisposition, for this was present to an ample degree in the lady I have in mind.

¹ I once learnt to my surprise that an 'abreaction of arrears' of this kind - though the impressions concerned were not derived from sick nursing - can form the subject-matter of an otherwise puzzling neurosis. This was so in the case of Fräulein Mathilde H., a good-looking, nineteen-year-old girl. When I first saw her she was suffering from a partial paralysis of the legs. Some months later, however, she came to me for treatment on account of a change in her character. She had become depressed to the point of a *taedium vitae*, utterly inconsiderate to her mother, irritable and inaccessible. The patient's picture as a whole forbade my assuming that this was a common melancholia. She was very easily put into a state of deep somnambulism, and I availed myself of this peculiarity of hers in order to give her commands and suggestions at every visit. She listened to these in deep sleep, to the accompaniment of floods of tears; but, apart from this, they caused very little change in her condition. One day she became talkative in her hypnosis and told me that the cause of her depression was the breaking off of her engagement, which had occurred several months earlier. Closer acquaintance with her fiancé had brought out more and more things that were unwelcome to her and her mother. On the other hand, the material advantages of the connection had been too obvious for it to be easy to decide to break it off. So for a long time they had both wavered and she herself had fallen into a state of indecision in which she regarded all that happened to her with apathy. In the end her mother uttered the decisive negative on her behalf. A little later she had woken up as though from a dream and begun to occupy her thoughts busily with the decision that had already been made and to weigh the pros and cons. This process, she told me, was still going on: she was living in the period of doubt, and every day she was possessed by the mood and thoughts which were appropriate to the day in the past with which she was occupied. Her irritability with her mother, too, had its basis only in the circumstances which prevailed at that time.: In comparison with these activities of her thoughts, her present life seemed like a mere appearance of reality, like something in a dream. - I did not succeed in inducing the girl to talk again. I continued to address her while she was in deep somnambulism and saw her burst into tears each time without ever answering me; and one day, round about the anniversary of her engagement, her whole state of depression passed off - an event which brought me the credit of a great therapeutic success by hypnotism.

But I must now return to Fräulein Elisabeth von R. While she was nursing her father, as we have seen, she for the first time developed a hysterical symptom - a pain in a particular area of her right thigh. It was possible by means of analysis to find an adequate elucidation of the mechanism of the symptom. It happened at a moment when the circle of ideas embracing her duties to her sick father came into conflict with the content of the erotic desire she was feeling at the time. Under the pressure of lively self-reproaches she decided in favour of the former, and in doing so brought about her hysterical pain.

According to the view suggested by the conversion theory of hysteria what happened may be described as follows. She repressed her erotic idea from consciousness and transformed the amount of its affect into physical sensations of pain. It did not become clear whether she was presented with this first conflict on one occasion only or on several; the latter alternative is the more likely. An exactly similar conflict - though of higher ethical significance and even more clearly established by the analysis - developed once more some years later and led to an intensification of the same pains and to an extension beyond their original limits. Once again it was a circle of ideas of an erotic kind that came into conflict with all her moral ideas; for her inclinations centred upon her brother-in-law, and, both during her sister's lifetime and after her death, the thought of being attracted by precisely this man was totally unacceptable to her. The analysis provided detailed information about this conflict, which constituted the central point in the history of the illness. The germs of the patient's feeling for her brother-in-law may have been present for a long time; its development was favoured by physical exhaustion owing to more sick-nursing and by moral exhaustion owing to disappointments extending over many years. The coldness of her nature began to yield and she admitted to herself her need for a man's love. During the several weeks which she passed in his company at the health resort her erotic feelings as well as her pains reached their full height.

The analysis, moreover, gave evidence that during the same period the patient was in a special psychical state. The connection of this state with her erotic feelings and her pains seems to make it possible to understand what happened on the lines of the conversion theory. It is, I think, safe to say that at that time the patient did not become clearly conscious of her feelings for her brother-in-law, powerful though they were, except on a few occasions, and then only momentarily. If it had been otherwise, she would also inevitably have become conscious of the contradiction between those feelings and her moral ideas and would have experienced mental torments like those I saw her go through after our analysis. She had no recollection of any such sufferings; she had avoided them. It followed that her feelings themselves did not become clear to her. At that time, as well as during the analysis, her love for her brother-in-law was present in her consciousness like a foreign body, without having entered into relationship with the rest of her ideational life. With regard to these feelings she was in the peculiar situation of knowing and at the same time not knowing - a situation, that is, in which a psychical group was cut off. But this and nothing else is what we mean when we say that these feelings were not clear to her. We do not mean that their consciousness was of a lower quality or of a lesser degree, but that they were cut off from any free associative connection of thought with the rest of the ideational content of her mind.

But how could it have come about that an ideational group with so much emotional emphasis on it was kept so isolated? In general, after all, the part played in association by an idea increases in proportion to the amount of its affect.

We can answer this question if we take into account two facts which we can make use of as being established with certainty. (1) Simultaneously with the formation of this separate psychical group the patient developed her hysterical pains. (2) The patient offered strong resistance to the attempt to bring about an association between the separate psychical group and the rest of the content of her consciousness; and when, in spite of this, the connection was accomplished she felt great psychical pain. Our view of hysteria brings these two facts into relation with the splitting of her consciousness by asserting that the second of them indicates the *motive* for the splitting of consciousness, while the first indicates its *mechanism*. The motive was that of defence, the refusal on the part of the patient's whole ego to come to terms with this ideational group. The mechanism was that of conversion: i.e. in place of the mental pains which she avoided, physical pains made their appearance. In this way a transformation was effected which had the advantage that the patient escaped from an intolerable mental condition; though, it is true, this was at the cost of a psychical abnormality - the splitting of consciousness that came about - and of a physical illness - her pains, on which an astasia-abasia was built up.

I cannot, I must confess, give any hint of how a conversion of this kind is brought about. It is obviously not carried out in the same way as an intentional and voluntary action. It is a process which occurs under the pressure of the motive of defence in someone whose organization - or a temporary modification of it - has a proclivity in that direction.

This theory calls for closer examination. We may ask: what is it that turns into physical pain here? A cautious reply would be: something that might have become, and should have become, *mental* pain. If we venture a little further and try to represent the ideational mechanism in a kind of algebraical picture, we may attribute a certain quota of affect to the ideational complex of these erotic feelings which remained unconscious, and say that this quantity (the quota of affect) is what was converted. It would follow directly from this description that the 'unconscious love' would have lost so much of its intensity through a conversion of this kind that it would have been reduced to no more than a weak idea. This reduction of strength would then have been the only thing which made possible the existence of these unconscious feelings as a separate psychical group. The present case, however, is not well fitted to give a clear picture of such a delicate matter. For in this case there was probably only partial conversion; in others it can be shown with likelihood that complete conversion also occurs, and that in it the incompatible idea has in fact been 'repressed', as only an idea of very slight intensity can be. The patients concerned declare, after associative connection with the incompatible idea has been established, that their thoughts had not been concerned with it since the appearance of the hysterical symptoms.

I have asserted that on certain occasions, though only for the moment, the patient recognized her love for her brother-in-law consciously. As an example of this we may recall the moment when she was standing by her sister's bed and the thought flashed through her mind: 'Now he is free and you can be his wife'. I must now consider the significance of these moments in their bearing on our view of the whole neurosis. It seems to me that the concept of a 'defence hysteria' in itself implies that at least *one* moment of this kind must have occurred. Consciousness, plainly, does not know in advance when an incompatible idea is going to crop up. The incompatible idea, which, together with its concomitants, is later excluded and forms a separate psychical group, must originally have been in communication with the main stream of thought. Otherwise the conflict which led to their exclusion could not have taken place.¹ It is these moments, then, that are to be described as 'traumatic': it is at these moments that conversion takes place, of which the results are the splitting of consciousness and the hysterical symptom. In the case of Fräulein Elisabeth von R. everything points to there having been several such moments - the scenes of the walk, the morning reverie, the bath, and at her sister's bedside. It is even possible that new moments of the same kind happened during the treatment. What makes it possible for there to be *several* of these traumatic moments is that an experience similar to the one which originally introduced the incompatible idea adds fresh excitation to the separated psychical group and so puts a temporary stop to the success of the conversion. The ego is obliged to attend to this sudden flare-up of the idea and to restore the former state of affairs by a further conversion. Fräulein Elisabeth, who was much in her brother-in-law's company, must have been particularly liable to the occurrence of fresh traumas. From the point of view of my present exposition, I should have preferred a case in which the traumatic history lay wholly in the past.

¹ It is otherwise in hypnoid hysteria, where the content of the separate psychical group would never have been in the ego-consciousness.

I must now turn to a point which I have described as offering a difficulty to the understanding of this case history. On the evidence of the analysis, I assumed that a first conversion took place while the patient was nursing her father, at the time when her duties as a nurse came into conflict with her erotic desires, and that what happened then was the prototype of the later events in the Alpine health resort which led to the outbreak of the illness. But it appeared from the patient's account that while she was nursing her father and during the time that followed - what I have described as the 'first period' - *she had no pains whatever and no locomotor weakness*. It is true that once during her father's illness she was laid up for a few days with pains in her legs, but it remained a question whether this attack was already to be ascribed to hysteria. No causal connection between these first pains and any psychical impression could be traced in the analysis. It is possible, and indeed probable, that what she was suffering from at that time were common rheumatic muscular pains. Moreover, even if we were inclined to suppose that this first attack of pains was the effect of a hysterical conversion as a result of the repudiation of her erotic thoughts at the time, the fact remains that the pains disappeared after only a few days, so that the patient had behaved differently in reality from what she seemed to indicate in the analysis. During her reproduction of what I have called the first period she accompanied all her stories about her father's illness and death, about her impressions of her dealings with her first brother-in-law, and so on, with manifestations of pain, whereas at the time of actually experiencing these impressions she had felt none. Is not this a contradiction which is calculated to reduce very considerably our belief in the explanatory value of an analysis such as this?

I believe I can solve this contradiction by assuming that the pains - the products of conversion - did not occur while the patient was experiencing the impressions of the first period, but only after the event, that is, in the second period, while she was reproducing those impressions in her thoughts. That is to say, the conversion did not take place in connection with her impressions when they were fresh, but in connection with her memories of them. I even believe that such a course of events is nothing unusual in hysteria and indeed plays a regular part in the genesis of hysterical symptoms. But since an assertion like this is not self-evident, I will try to make it more plausible by bringing forward some other instances.

It once happened to me that a new hysterical symptom developed in a patient during the actual course of an analytic treatment of this kind so that I was able to set about getting rid of it on the day after its appearance. I will interpolate the main features of the case at this point. It was a fairly simple one, yet not without interest.

Fräulein Rosalia H., aged twenty-three, had for some years been undergoing training as a singer. She had a good voice, but she complained that in certain parts of its compass it was not under her control. She had a feeling of choking and constriction in her throat so that her voice sounded tight. For this reason her teacher had not yet been able to consent to her appearing as a singer in public. Although this imperfection affected only her middle register, it could not be attributed to a defect in the organ itself. At times the disturbance was completely absent and her teacher expressed great satisfaction; at other times, if she was in the least agitated, and sometimes without any apparent cause, the constricted feeling would reappear and the production of her voice was impeded. It was not difficult to recognize a hysterical conversion in this very troublesome feeling. I did not take steps to discover whether there was in fact a contracture of some of the muscles of the vocal cords.¹ In the course of the hypnotic analysis which I carried out with the girl, I learned the following facts about her history and consequently about the cause of her trouble. She lost her parents early in life and was taken to live with an aunt who herself had numerous children. In consequence of this she became involved in a most unhappy family life. Her aunt's husband, who was a manifestly pathological person, brutally ill-treated his wife and children. He wounded their feelings more particularly by the way in which he showed an open sexual preference for the servants and nursemaids in the house; and the more the children grew up the more offensive this became. After her aunt's death Rosalia became the protector of the multitude of children who were now orphaned and oppressed by their father. She took her duties seriously and fought through all the conflicts into which her position led her, though it required a great effort to suppress the hatred and contempt which she felt for her uncle.² It was at this time that the feeling of constriction in her throat started. Every time she had to keep back a reply, or forced herself to remain quiet in the face of some outrageous accusation, she felt a scratching in her throat, a sense of constriction, a loss of voice - all the sensations localized in her larynx and pharynx which now interfered with her singing. It was not to be wondered at that she sought an opportunity of making herself independent and escaping the agitations and distressing experiences which were of daily occurrence in her uncle's house. A highly competent teacher of singing came to her assistance disinterestedly and assured her that her voice justified her in choosing the profession of singer. She now began to take lessons with him in secret. But she used often to hurry off to her singing lesson while she still had the constriction in her throat that used to be left over after violent scenes at home. Consequently a connection was firmly established between her singing and her hysterical paraesthesia - a connection for which the way was prepared by the organic sensations set up by singing. The apparatus over which she ought to have had full control when she was singing turned out to be cathected with residues of innervations left over from the numerous scenes of suppressed emotion. Since then, she had left her uncle's house and had moved to another town in order to be away from her family. But this did not get over her difficulty.

¹ I had another case of a singer under my observation in which a contracture of the masseters made it impossible for her to practise her art. This young woman had been obliged to go on the stage by unfortunate events in her family. She was singing at a rehearsal in Rome at a time when she was in a state of great emotional excitement, and suddenly had a feeling that she could not close her open mouth and fell to the floor in a faint. The doctor who was called in brought her jaws together forcibly. But thenceforward the patient was unable to open her jaws by more than a finger's breadth and had to give up her new profession. When, several years later, she came to me for treatment, the causes of her emotional excitement had obviously long since disappeared, for some massage while she was in a state of light hypnosis sufficed to enable her mouth to open wide. Since then the lady has sung in public.

² [Footnote added 1924:] In this instance, too, it was in fact the girl's father, not her uncle.

This good-looking and unusually intelligent girl exhibited no other hysterical symptoms.

I did my best to get rid of this 'retention hysteria' by getting her to reproduce all her agitating experiences and to abreact them after the event. I made her abuse her uncle, lecture him, tell him the unvarnished truth, and so on, and this treatment did her good. Unfortunately, however, she was living in Vienna under very unfavourable conditions. She had no luck with her relatives. She was being put up by another uncle, who treated her in a friendly way; but for that very reason her aunt took a dislike to her. This woman suspected that her husband had a deeper interest in his niece, and therefore chose to make her stay in Vienna as disagreeable as possible. The aunt herself in her youth had been obliged to give up a desire for an artistic career and envied her niece for being able to cultivate her talent, though in the girl's case it was not her desire but her need for independence that had determined her decision. Rosalie felt so constrained in the house that she did not venture, for instance, to sing or play the piano while her aunt was within earshot and carefully avoided singing or playing to her uncle (who, incidentally, was an old man, her mother's brother) when there was a possibility of her aunt coming in. While I was trying to wipe out the traces of old agitations, new ones arose out of these relations with her host and hostess, which eventually interfered with the success of my treatment as well as bringing it to a premature end.

One day the patient came for her session with a new symptom, scarcely twenty-four hours old. She complained of a disagreeable pricking sensation in the tips of her fingers, which, she said, had been coming on every few hours since the day before and compelled her to make a peculiar kind of twitching movement with her fingers. I was not able to observe an attack; otherwise I should no doubt have been able to guess from the nature of the movements what it was that had occasioned them. But I immediately tried to get on the track of the explanation of the symptom (it was in fact a minor hysterical attack) by hypnotic analysis. Since the whole thing had only been in existence such a short time I hoped that I should quickly be able to explain and get rid of the symptom. To my astonishment the patient produced a whole number of scenes, without hesitation and in chronological order, beginning with her early childhood. They seemed to have in common her having had some injury done to her, against which she had not been able to defend herself, and which might have made her fingers jerk. They were such scenes, for instance, as of having had to hold out her hand at school and being struck on it with a ruler by her teacher. But they were quite ordinary occasions and I should have been prepared to deny that they could play a part in the aetiology of a hysterical symptom. But it was otherwise with one scene from her girlhood which followed. Her bad uncle, who was suffering from rheumatism, had asked her to massage his back and she did not dare to refuse. He was lying in bed at the time, and suddenly threw off the bed-clothes, sprang up and tried to catch hold of her and throw her down. Massage, of course, was at an end, and a moment later she had escaped and locked herself in her room. She was clearly loth to remember this and was unwilling to say whether she had seen anything when he suddenly uncovered himself. The sensations in her fingers might be explained in this case by a suppressed impulse to punish him, or simply by her having been engaged in massaging him at the time. It was only after relating this scene that she came to the one of the day before, after which the sensations and jerking in her fingers had set in as a recurrent mnemonic symbol. The uncle with whom she was now living had asked her to play him something. She sat down to the piano and accompanied herself in a song, thinking that her aunt had gone out; but suddenly she appeared in the door. Rosalie jumped up, slammed the lid of the piano and threw the music away. We can guess what the memory was that rose in her mind and what the train of thought was that she was fending off at that moment: it was a feeling of violent resentment at the unjust suspicion to which she was subjected and which should have made her leave the house, while in fact she was obliged to stay in Vienna on account of the treatment and had nowhere else where she could be put up. The movement of her fingers which I saw her make while she was reproducing this scene was one of twitching something away, in the way in which one literally and figuratively brushes something aside - tosses away a piece of paper or rejects a suggestion.

She was quite definite in her insistence that she had not noticed this symptom previously - that it had not been occasioned by the scenes she had first described. We could only suppose, therefore, that the event of the previous day had in the first instance aroused the memory of earlier events with a similar subject-matter and that thereupon a mnemonic symbol had been formed which applied to the whole group of memories. The energy for the conversion had been supplied, on the one hand, by freshly experienced affect and, on the other hand, by recollected affect.

When we consider the question more closely we must recognize that a process of this kind is the rule rather than the exception in the genesis of hysterical symptoms. Almost invariably when I have investigated the determinants of such conditions what I have come upon has not been a *single* traumatic cause but a group of similar ones. (This is well exemplified in the case of Frau Emmy - Case History 2.) In some of these instances it could be established that the symptom in question had already appeared for a short time after the first trauma and had then passed off, till it was brought on again and stabilized by a succeeding trauma. There is, however, in principle no difference between the symptom appearing in this temporary way after its first provoking cause and its being latent from the first. Indeed, in the great majority of instances we find that a first trauma has left no symptom behind, while a later trauma of the same kind produces a symptom, and yet that the latter could not have come into existence without the co-operation of the earlier provoking cause; nor can it be cleared up without taking all the provoking causes into account.

Stated in terms of the conversion theory, this incontrovertible fact of the summation of traumas and of the preliminary latency of symptoms tells us that conversion can result equally from fresh symptoms and from recollected ones. This hypothesis completely explains the apparent contradiction that we observed between the events of Fräulein Elisabeth von R.'s illness and her analysis. There is no doubt that the continued existence in consciousness of ideas whose affect has not been dealt with can be tolerated by healthy individuals up to a great amount. The view which I have just been putting forward does no more than bring the behaviour of hysterical people nearer to that of healthy ones. What we are concerned with is clearly a quantitative factor - the question of how much affective tension of this kind an organism can tolerate. Even a hysteric can retain a certain amount of affect that has not been dealt with; if, owing to the occurrence of similar provoking causes, that amount is increased by summation to a point beyond the subject's tolerance, the impetus to conversion is given. Thus when we say that the construction of hysterical symptoms can proceed on the strength of recollected affects as well as fresh ones, we shall not be making any unfamiliar assertion, but stating something that is almost accepted as a postulate.

I have now discussed the motives and mechanism of this case of hysteria; it remains for me to consider how precisely the hysterical symptom was determined. Why was it that the patient's mental pain came to be represented by pains in the legs rather than elsewhere? The circumstances indicate that this somatic pain was not *created* by the neurosis but merely used, increased and maintained by it. I may add at once that I have found a similar state of things in almost all the instances of hysterical pains into which I have been able to obtain an insight. There had always been a genuine, organically-founded pain present at the start. It is the commonest and most widespread human pains that seem to be most often chosen to play a part in hysteria: in particular, the periosteal and neuralgic pains accompanying dental disease, the headaches that arise from so many different sources and, not less often, the rheumatic muscular pains that are so often unrecognized. In the same way I attribute an organic foundation to Fräulein Elisabeth von R.'s first attack of pain which occurred as far back as while she was nursing her father. I obtained no result when I tried to discover a psychical cause for it - and I am inclined, I must confess, to attribute a power of differential diagnosis to my method of evoking concealed memories, provided it is carefully handled. This pain, which was rheumatic in its origin,¹ then became a mnemonic symbol of her painful psychical excitations; and this happened, so far as I can see, for more than one reason. The first and no doubt the most important of these reasons was that the pain was present in her consciousness at about the same time as the excitations. In the second place, it was connected, or could be connected, along a number of lines with the ideas in her mind at the time. The pain, indeed, may actually have been a consequence, though only a remote one, of the period of nursing - of the lack of exercise and reduced diet that her duties as a sick-nurse entailed. But the girl had no clear knowledge of this. More importance should probably be attached to the fact that she must have felt the pain during that time at significant moments, for instance, when she sprang out of bed in the cold of winter in response to a call from her father. But what must have had a positively decisive influence on the direction taken by the conversion was another line of associative connection: the fact that on a long succession of days one of her painful legs came into contact with her father's swollen leg while his bandages were being changed. The area of her right leg which was marked out by this contact remained thereafter the focus of her pains and the point from which they radiated. It formed an artificial hysterogenic zone whose origin could in the present case be clearly observed.

If anyone feels astonished at this associative connection between physical pain and psychical affect, on the ground of its being of such a multiple and artificial character, I should reply that this feeling is as little justified as astonishment at the fact that it is the rich people who own the most money. Where there are no such numerous connections a hysterical symptom will not, in fact, be formed; for conversion will find no path open to it. And I can affirm that the example of Fräulein Elisabeth von R. was among the simpler ones as regards its determination. I have had the most tangled threads to unravel, especially in the case of Frau Cécilie M.

¹ It may, however, have been of a spinal-neurasthenic sort.

I have already discussed in the case history the way in which the patient's astasia-abasia was built up on these pains, after a particular path had been opened up for the conversion. In that passage, however, I also expressed my view that the patient had created, or increased, her functional disorder by means of symbolization, that she had found in the astasia-abasia a somatic expression for her lack of an independent position and her inability to make any alteration in her circumstances, and that such phrases as 'not being able to take a single step forward', 'not having anything to lean upon', served as the bridge for this fresh act of conversion.

I shall try to support this view by other examples. Conversion on the basis of simultaneity, where there is also an associative link, seems to make the smallest demands on a hysterical disposition; conversion by symbolization, on the other hand, seems to call for the presence of a higher degree of hysterical modification. This could be observed in the case of Fräulein Elisabeth, but only in the later stage of her hysteria. The best examples of symbolization that I have seen occurred in Frau Căcilie M., whose case I might describe as my most severe and instructive one. I have already explained that a detailed report of her illness is unfortunately impossible.

Frau Căcilie suffered among other things from an extremely violent facial neuralgia which appeared suddenly two or three times a year, lasted for from five to ten days, resisted any kind of treatment and then ceased abruptly. It was limited to the second and third branches of one trigeminal, and since an abnormal excretion of urates was undoubtedly present and a not quite clearly defined 'acute rheumatism' played some part in the patient's history, a diagnosis of gouty neuralgia was plausible enough. This diagnosis was confirmed by the different consultants who were called in at each attack. Treatment of the usual kind was ordered: the electric brush, alkaline water, purges; but each time the neuralgia remained unaffected until it chose to give place to another symptom. Earlier in her life - the neuralgia was fifteen years old - her teeth were accused of being responsible for it. They were condemned to extraction, and one fine day, under narcosis, the sentence was carried out on seven of the criminals. This was not such an easy matter; her teeth were so firmly attached that the roots of most of them had to be left behind. This cruel operation had no result, either temporary or permanent. At that time the neuralgia raged for months on end. Even at the time of my treatment, at each attack of neuralgia the dentist was called in. On each occasion he diagnosed the presence of diseased roots and began to get to work on them; but as a rule he was soon interrupted. For the neuralgia would suddenly cease, and at the same time the demand for the dentist's services. During the interval her teeth did not ache at all. One day, when an attack was raging once more, the patient got me to give her hypnotic treatment. I laid a very energetic prohibition on her pains, and from that moment they ceased. I began at that time to harbour doubts of the genuineness of the neuralgia.

About a year after this successful hypnotic treatment Frau Cäcilie's illness took a new and surprising turn. She suddenly developed new pathological states, different from those that had characterized the last few years. But after some reflection the patient declared that she had had all of them before at various times during the course of her long illness, which had lasted for thirty years. There now developed a really surprising wealth of hysterical attacks which the patient was able to assign to their right place in her past. And soon, too, it was possible to follow the often highly involved trains of thought that determined the order in which these attacks occurred. They were like a series of pictures with explanatory texts. Pitres must have had something of the sort in mind in putting forward his description of what he termed '*délire écmnésique*'. It was most remarkable to see the way in which a hysterical state of this kind belonging to the past was reproduced. There first came on, while the patient was in the best of health, a pathological mood with a particular colouring which she regularly misunderstood and attributed to some commonplace event of the last few hours. Then, to the accompaniment of an increasing clouding of consciousness, there followed hysterical symptoms: hallucinations, pains, spasms and long declamatory speeches. Finally, these were succeeded by the emergence in a hallucinatory form of an experience from the past which made it possible to explain her initial mood and what had determined the symptoms of her present attack. With this last piece of the attack her clarity of mind returned. Her troubles disappeared as though by magic and she felt well once again - till the next attack, half a day later. As a rule I was sent for at the climax of the attack, induced a state of hypnosis, called up the reproduction of the traumatic experience and hastened the end of the attack by artificial means. Since I assisted at several hundreds of such cycles with the patient, I gained the most instructive information on the way in which hysterical symptoms are determined. Indeed, it was the study of this remarkable case, jointly with Breuer, that led directly to the publication of our 'Preliminary Communication'.

In this phase of the work we came at last to the reproduction of her facial neuralgia, which I myself had treated when it appeared in contemporary attacks. I was curious to discover whether this, too, would turn out to have a psychical cause. When I began to call up the traumatic scene, the patient saw herself back in a period of great mental irritability towards her husband. She described a conversation which she had had with him and a remark of his which she had felt as a bitter insult. Suddenly she put her hand to her cheek, gave a loud cry of pain and said: 'It was like a slap in the face.' With this her pain and her attack were both at an end.

There is no doubt that what had happened had been a symbolization. She had felt as though she had actually been given a slap in the face. Everyone will immediately ask how it was that the sensation of a 'slap in the face' came to take on the outward forms of a trigeminal neuralgia, why it was restricted to the second and third branches, and why it was made worse by opening the mouth and chewing - though, incidentally, not by talking.

Next day the neuralgia was back again. But this time it was cleared up by the reproduction of *another* scene, the content of which was once again a supposed insult. Things went on like this for nine days. It seemed to be the case that for years insults, and particularly spoken ones, had, through symbolization, brought on fresh attacks of her facial neuralgia.

But ultimately we were able to make our way back to her first attack of neuralgia, more than fifteen years earlier. Here there was no symbolization but a conversion through simultaneity. She saw a painful sight which was accompanied by feelings of self-reproach, and this led her to force back another set of thoughts. Thus it was a case of conflict and defence. The generation of the neuralgia at that moment was only explicable on the assumption that she was suffering at the time from slight toothache or pains in the face, and this was not improbable, since she was just then in the early months of her first pregnancy.

Thus the explanation turned out to be that this neuralgia had come to be indicative of a particular psychical excitation by the usual method of conversion, but that afterwards it could be set going through associative reverberations from her mental life, or symbolic conversion. In fact, the same behaviour that we found in Fräulein Elisabeth von R.

I will give a second example which demonstrates the action of symbolization under other conditions. At a particular period, Frau Căcilie was afflicted with a violent pain in her right heel - a shooting pain at every step she took, which made walking impossible. Analysis led us in connection with this to a time when the patient had been in a sanatorium abroad. She had spent a week in bed and was going to be taken down to the common dining-room for the first time by the house physician. The pain came on at the moment when she took his arm to leave the room with him; it disappeared during the reproduction of the scene, when the patient told me she had been afraid at the time that she might not 'find herself on a right footing' with these strangers.

This seems at first to be a striking and even a comic example of the genesis of hysterical symptoms through symbolization by means of a verbal expression. Closer examination of the circumstances, however, favours another view of the case. The patient had been suffering at the time from pains in the feet generally, and it was on their account that she had been confined to bed so long. All that could be claimed on behalf of symbolization was that the fear which overcame the patient, as she took her first steps, picked out from among all the pains that were troubling her at the time the one particular pain which was symbolically appropriate, the pain in her right heel, and developed it into a psychical pain and gave it special persistence.

In these examples the mechanism of symbolization seems to be reduced to secondary importance, as is no doubt the general rule. But I have examples at my disposal which seem to prove the genesis of hysterical symptoms through symbolization alone. The following is one of the best, and relates once more to Frau Căcilie. When a girl of fifteen, she was lying in bed, under the watchful eye of her strict grandmother. The girl suddenly gave a cry; she had felt a penetrating pain in her forehead between her eyes, which lasted for weeks. During the analysis of this pain, which was reproduced after nearly thirty years, she told me that her grandmother had given her a look so 'piercing' that it had gone right into her brain. (She had been afraid that the old woman was viewing her with suspicion.) As she told me this thought she broke into a loud laugh, and the pain once more disappeared. In this instance I can detect nothing other than the mechanism of symbolization, which has its place, in some sense, midway between autosuggestion and conversion.

My observation of Frau Căcilie M. gave me an opportunity of making a regular collection of symbolizations of this kind. A whole set of physical sensations which would ordinarily be regarded as organically determined were in her case of psychical origin or at least possessed a psychical meaning. A particular series of experiences of hers were accompanied by a stabbing sensation in the region of the heart (meaning 'it stabbed me to the heart'). The pain that occurs in hysteria of nails being driven into the head was without any doubt to be explained in her case as a pain related to thinking. ('Something's come into my head.') Pains of this kind were always cleared up as soon as the problems involved were cleared up. Running parallel to the sensation of a hysterical 'aura' in the throat, when that feeling appeared after an insult, was the thought 'I shall have to swallow this'. She had a whole quantity of sensations and ideas running parallel with each other. Sometimes the sensation would call up the idea to explain it, sometimes the idea would create the sensation by means of symbolization, and not infrequently it had to be left an open question which of the two elements had been the primary one.

I have not found such an extensive use of symbolization in any other patient. It is true that Frau Cécilie M. was a woman who possessed quite unusual gifts, particularly artistic ones, and whose highly developed sense of form was revealed in some poems of great perfection. It is my opinion, however, that when a hysteric creates a somatic expression for an emotionally coloured idea by symbolization, this depends less than one would imagine on personal or voluntary factors. In taking a verbal expression literally and in feeling the 'stab in the heart' or the 'slap in the face' after some slighting remark as a real event, the hysteric is not taking liberties with words, but is simply reviving once more the sensations to which the verbal expression owes its justification. How has it come about that we speak of someone who has been slighted as being 'stabbed to the heart' unless the slight had in fact been accompanied by a precordial sensation which could suitably be described in that phrase and unless it was identifiable by that sensation? What could be more probable than that the figure of speech 'swallowing something', which we use in talking of an insult to which no rejoinder has been made, did in fact originate from the innervatory sensations which arise in the pharynx when we refrain from speaking and prevent ourselves from reacting to the insult? All these sensations and innervations belong to the field of 'The Expression of the Emotions', which, as Darwin has taught us, consists of actions which originally had a meaning and served a purpose. These may now for the most part have become so much weakened that the expression of them in words seems to us only to be a figurative picture of them, whereas in all probability the description was once meant literally; and hysteria is right in restoring the original meaning of the words in depicting its unusually strong innervations. Indeed, it is perhaps wrong to say that hysteria creates these sensations by symbolization. It may be that it does not take linguistic usage as its model at all, but that both hysteria and linguistic usage alike draw their material from a common source.¹

¹ In states in which mental alteration goes deeper, we clearly also find a symbolic version in concrete images and sensations of more artificial turns of speech. Frau Cécilie M. passed through a period during which she transformed every thought she had into a hallucination, the explanation of which often called for much ingenuity. She complained to me at that time of being troubled by a hallucination that her two doctors - Breuer and I - were hanging on two trees next each other in the garden. The hallucination disappeared after the analysis had brought out the following explanation. The evening before, Breuer had refused to give her a drug she had asked for. She had then set her hopes on me but had found me equally hard-hearted. She was furious with us over this, and in her anger she thought to herself: 'There's nothing to choose between the two of them; one's the *pendant* [match] of the other.'

Studies On Hysteria

III

THEORETICAL

(BREUER)

In the 'Preliminary Communication' which introduces this work we laid down the conclusions to which we were led by our observations, and I think that I can stand by them in the main. But the 'Preliminary Communication' is so short and concise that for the most part it was only possible in it to hint at our views. Now, therefore, that the case histories have brought forward evidence in support of our conclusions it may be permissible to state them at greater length. Even here, there is, of course, no question of dealing with the *whole* field of hysteria. But we may give a somewhat closer and clearer account (with some added reservations, no doubt) of those points for which insufficient evidence was adduced or which were not given enough prominence in the 'Preliminary Communication'.

In what follows little mention will be made of the brain and none whatever of molecules. Psychical processes will be dealt with in the language of psychology; and, indeed, it cannot possibly be otherwise. If instead of 'idea' we chose to speak of 'excitation of the cortex', the latter term would only have any meaning for us in so far as we recognized an old friend under that cloak and tacitly reinstated the 'idea'. For while ideas are constant objects of our experience and are familiar to us in all their shades of meaning, 'cortical excitations' are on the contrary rather in the nature of a postulate, objects which we hope to be able to identify in the future. The substitution of one term for another would seem to be no more than a pointless disguise. Accordingly, I may perhaps be forgiven if I make almost exclusive use of psychological terms.

There is another point for which I must ask in advance for the reader's indulgence. When a science is making rapid advances, thoughts which were first expressed by single individuals quickly become common property. Thus no one who attempts to put forward to-day his views on hysteria and its psychical basis can avoid repeating a great quantity of other people's thoughts which are in the act of passing from personal into general possession. It is scarcely possible always to be certain who first gave them utterance, and there is always a danger of regarding as a product of one's own what has already been said by someone else. I hope, therefore, that I may be excused if few quotations are found in this discussion and if no strict distinction is made between what is my own and what originates elsewhere. Originality is claimed for very little of what will be found in the following pages.

(1) ARE ALL HYSTERICAL PHENOMENA IDEOGENIC?

In our 'Preliminary Communication' we discussed the psychical mechanism of 'hysterical phenomena', not of 'hysteria', because we did not wish to claim that this psychical mechanism or the psychical theory of hysterical symptoms in general has unlimited validity. We are not of the opinion that all the phenomena of hysteria come about in the manner described by us in that paper, nor do we believe that they are all ideogenic, that is, determined by ideas. In this we differ from Moebius, who in 1888 proposed to define as hysterical all pathological phenomena that are caused by ideas. This statement was later elucidated to the effect that only a part of the pathological phenomena correspond in their content to the ideas that cause them - those phenomena, namely, that are produced by allo- or auto-suggestion, as, for instance, when the idea of not being able to move one's arm causes a paralysis of it; while another part of the hysterical phenomena, though caused by ideas, do not correspond to them in their content - as, for instance, when in one of our patients a paralysis of the arm was caused by the sight of snake-like objects.

In giving this definition, Moebius is not merely proposing a modification in nomenclature and suggesting that in future we should only describe as hysterical those pathological phenomena which are ideogenic (determined by ideas); what he thinks is that all hysterical symptoms are ideogenic. 'Since ideas are very frequently the cause of hysterical phenomena, I believe that they always are.' He terms this an inference by analogy. I prefer to call it a generalization, the justification for which must first be tested.

Before any discussion of the subject, we must obviously decide what we understand by hysteria. I regard hysteria as a clinical picture which has been empirically discovered and is based on observation, in just the same way as tubercular pulmonary phthisis. Clinical pictures of this kind that have been arrived at empirically are made more precise, deeper and clearer by the progress of our knowledge; but they ought not to be and cannot be disrupted by it. Aetiological research has shown that the various constituent processes of pulmonary phthisis have various causes: the tubercle is due to *bacillus Kochii*, and the disintegration of tissue, the formation of cavities and the septic fever are due to other microbes. In spite of this, tubercular phthisis remains a clinical unity and it would be wrong to break it up by attributing to it only the 'specifically tubercular' modifications of tissue caused by Koch's bacillus and by detaching the other modifications from it. In the same way hysteria must remain a clinical unity even if it turns out that its phenomena are determined by various causes, and that some of them are brought about by a psychical mechanism and others without it.

It is my conviction that this is in fact so; only a part of the phenomena of hysteria are ideogenic, and the definition put forward by Moebius tears in half the clinical unity of hysteria, and indeed the unity of one and the same symptom in the same patient.

We should be drawing an inference completely analogous to Moebius's 'inference by analogy' if we were to say that because ideas and perceptions very often give rise to erections we may assume that they alone ever do so and that peripheral stimuli set this vasomotor process in action only by a roundabout path through the psyche. We know that this inference would be false, yet it is based on at least as many facts as Moebius's assertion about hysteria. In conformity with our experience of a large number of physiological processes, such as the secretion of saliva or tears, changes in the action of the heart, etc., it is possible and plausible to assume that one and the same process may be set in motion equally by ideas and by peripheral and other non-psychical stimuli. The contrary would need to be proved and we are very far short of that. Indeed, it seems certain that many phenomena which are described as hysterical are not caused by ideas alone.

Let us consider an everyday instance. A woman may, when ever an affect arises, produce on her neck, breast and face an erythema appearing first in blotches and then becoming confluent. This is determined by ideas and therefore according to Moebius is a hysterical phenomenon. But this same erythema appears, though over a less extensive area, when the skin is irritated or touched, etc. This would *not* be hysterical. Thus a phenomenon which is undoubtedly a complete unity would of one occasion be hysterical and on another occasion not. It may of course be questioned whether this phenomenon, the erethism of the vasomotors, should be regarded as a specifically hysterical one or whether it should not be more properly looked upon simply as 'nervous'. But on Moebius's view the breaking up of the unity would necessarily result in any case and the affectively-determined erythema would alone be called hysterical.

This applies in exactly the same way to the hysterical pain which are of so much practical importance. No doubt these are often determined directly by ideas. They are 'hallucinations of pain'. If we examine these rather more closely it appears that the fact of an idea being very vivid is not enough to produce them but that there must be a special abnormal condition of the apparatuses concerned with the conduction and sensation of pain, just as in the case of affective erythema an abnormal excitability of the vasomotors must be present. The phrase 'hallucinations of pain' undoubtedly gives the most pregnant description of the nature of these neuralgias, but it compels us too, to carry over to them the views that we have formed of hallucinations in general. A detailed discussion of these views would not be in place here. I subscribe to the opinion that 'ideas', mnemonic images pure and simple, without any excitation of the perceptual apparatus, never, even at their greatest vividness and intensity, attain the character of objective existence which is the mark of hallucinations.¹

¹ This perceptual apparatus, including the sensory areas of the cortex, must be different from the organ which stores up and reproduces sense-impressions in the form of mnemonic images. For the basic essential of the function of the perceptual apparatus is that its *status quo ante* should be capable of being restored with the greatest possible rapidity; otherwise no proper further perception could take place. The essential of memory, on the other hand, is that no such restoration should occur but that every perception should create changes that are permanent. It is impossible for one and the same organ to fulfil these two contradictory conditions. The mirror of a reflecting telescope cannot at the same time be a photographic plate. I am in agreement with Meynert, in the sense of believing, as I have said, that what gives hallucinations their objective character is an excitation of the perceptual apparatus (though I do not agree with him when he speaks of an excitation of the subcortical centres). If the perceptual organ is excited by a mnemonic image, we must suppose that that organ's excitability has been changed in an abnormal direction, and that this change is what makes hallucination possible.

This applies to sensory hallucinations and still more to hallucinations of pain. For it does not seem possible for a healthy person to endow the memory of a physical pain with even the degree of vividness, the distant approximation to the real sensation, which can, after all, be attained by optical and acoustic mnemonic images. Even in the normal hallucinatory state of healthy people which occurs in sleep there are never, I believe, dreams of pain unless a real sensation of pain is present. This 'retrogressive' excitation, emanating from the organ of memory and acting on the perceptual apparatus by means of ideas, is therefore in the normal course of things still more difficult in the case of pain than in that of visual or auditory sensations. Since hallucinations of pain arise so easily in hysteria, we must posit an abnormal excitability of the apparatus concerned with sensations of pain.

This excitability makes its appearance not only under the spur of ideas but of peripheral stimuli in just the same way as the erethism of the vasomotors which we discussed above.

It is a matter of daily observation to find that in people with normal nerves peripheral pains are brought on by pathological processes, not in themselves painful, in other organs. Thus headaches arise from relatively insignificant changes in the nose or neighbouring cavities, and again, neuralgias of the intercostal and brachial nerves from the heart, etc. If the abnormal excitability, which we have been obliged to postulate as a necessary condition of hallucinations of pain, is present in a patient, that excitability is also at the disposal, so to speak, of the irradiations that I have just mentioned. The irradiations that occur also in non-neurotic people are made more intense, and irradiations are formed of a sort which, it is true, we only find in neurotic patients but which are based on the same mechanism as the others. Thus, ovarian neuralgia depends, I believe, on states of the genital apparatus. That its causes are psychical would have to be proved, and this is not achieved by showing that that particular kind of pain, like any other, can be produced under hypnosis as a hallucination, or that its cause can be psychical. Like erythema or one of the normal secretions, it arises both from psychical and from purely somatic causes. Are we to describe only the first kind as hysterical - cases which we know have a psychical origin? If so, the commonly observed cases of ovarian neuralgia would have to be excluded from the hysterical syndrome, and this will hardly do.

If a slight injury to a joint is gradually followed by a severe arthralgia, no doubt the process involves a psychical element viz. a concentration of attention on the injured part, which intensifies the excitability of the nerve tracts concerned. But this can hardly be expressed by saying that the hyperalgesia has been caused by ideas.

The same is true of the pathological *diminution* of sensation. It is quite unproved and improbable that general analgesia or analgesia of individual parts of the body unaccompanied by anaesthesia is caused by ideas. And even if the discoveries of Binet and Janet were to be fully confirmed to the effect that hemi-anaesthesia is determined by a peculiar psychical condition, by a splitting of the psyche, the phenomenon would be a psychogenic but not an ideogenic one, and therefore, according to Moebius, should not be termed hysterical.

If, therefore, there are a large number of characteristic hysterical phenomena which we cannot suppose to be ideogenic, it would seem right to limit the application of Moebius's thesis. We shall not define as hysterical those pathological phenomena which are caused by ideas, but only assert that a great number of hysterical phenomena, probably more than we suspect to-day, are ideogenic. But the fundamental pathological change which is present in every case and enables ideas as well as non-psychological stimuli to produce pathological effects lies in an abnormal excitability of the nervous system.¹ How far this excitability is itself of psychical origin is another question.

Yet even though only some of the phenomena of hysteria are ideogenic, nevertheless it is precisely they that may be described as the specifically hysterical ones, and it is the investigation of them, the discovery of their psychical origin, which constitutes the most important recent step forward in the theory of the disorder. The further question then arises: how do these phenomena come about? What is their 'psychical mechanism'?

This question requires a quite different answer in the case of each of the two groups into which Moebius divides ideogenic symptoms. Those pathological phenomena which correspond in their content to the instigating idea are relatively understandable and clear. If the idea of a heard voice does not merely cause it to echo faintly in the 'inward ear', as it does in healthy people, but causes it to be perceived in a hallucinatory manner as a real, objective acoustic sensation, this may be equated with familiar phenomena of normal life - with dreams - and is quite intelligible on the hypothesis of abnormal excitability. We know that with every voluntary movement it is the idea of the result to be achieved which initiates the relevant muscular contraction; and it is not very hard to see that the idea that this contraction is impossible will impede the movement (as happens in paralysis by suggestion).

The situation is otherwise with those phenomena which have no logical connection with the determining idea. (Here, too, normal life offers parallels, as, for instance, blushing for shame.) How do they arise? Why does an idea in a sick man evoke one particular entirely irrational movement or hallucination which does not in any way correspond to it?

¹ Attributed by Oppenheim to 'instability of the molecules'. It may be possible at a later stage to replace the very vague statement in the text above by a more precise and significant formula.

In our 'Preliminary Communication' we felt able to say something about this causal relation on the basis of our observations. In our exposition of the subject, however, we introduced and employed without apology the concept of 'excitations which flow away or have to be abreacted'. This concept is of fundamental importance for our theme and for the theory of the neuroses in general, and it seems to demand and to deserve a more detailed examination. Before I proceed to this, I must ask to be forgiven for taking the reader back to the basic problems of the nervous system. A feeling of oppression is bound to accompany any such descent to the 'Mothers'.

But any attempt at getting at the roots of a phenomenon inevitably leads in this way to basic problems which cannot be evaded. I hope therefore that the abstruseness of the following discussion may be viewed with indulgence.

(2) INTRACEREBRAL TONIC EXCITATIONS - AFFECTS

(A)

We know two extreme conditions of the central nervous system: a clear waking state and dreamless sleep. A transition between these is afforded by conditions of every degree of decreasing clarity. What interests us here is not the question of the purpose of sleep and its physical basis (its chemical or vasomotor determinants) but the question of the essential distinction between the two conditions.

We can give no direct information about the deepest, dreamless sleep, for the very reason that all observations and experiences are excluded by the state of total unconsciousness. But as regards the neighbouring condition of sleep accompanied by dreams, the following assertions can be made. In the first place, when in that condition we intend to make voluntary movements - of walking, speaking, etc. - this does not result in the corresponding contractions of the muscles being voluntarily initiated, as they are in waking life. In the second place, sensory stimuli are perhaps perceived (for they often make their way into dreams) but they are not apperceived, i.e. do not become conscious perceptions. Again, ideas that emerge do not, as in waking life, activate all the ideas which are connected with them and which are present in potential consciousness; a great number of the latter remain unexcited. (For instance, we find ourselves talking to a dead person without remembering that he is dead.) Furthermore, incompatible ideas can be present simultaneously without mutually inhibiting each other, as they do in waking life. Thus, association is defective and incomplete. We may safely assume that in the deepest sleep this severance of connections between the psychical elements is carried still further and becomes total.

On the other hand, when we are fully awake every act of will initiates the corresponding movement; sense-impressions become conscious perceptions; and ideas are associated with the whole store present in potential consciousness. In that condition the brain functions as a unit with complete internal connections.

We shall perhaps only be describing these facts in other words if we say that in sleep the paths of connection and conduction in the brain are not traversable by excitations of the psychical elements (? cortical cells), whereas in waking life they are completely so traversable.

The existence of these two different conditions of the paths of conduction can, it seems, only be made intelligible if we suppose that in waking life those paths are in a state of tonic excitation (what Exner calls 'intercellular tetanus'), that this intracerebral excitation is what determines their conductive capability, and that the diminution and disappearance of that excitation is what sets up the state of sleep.

We ought not to think of a cerebral path of conduction as resembling a telephone wire which is only excited electrically at the moment at which it has to function (that is, in the present context, when it has to transmit a signal). We ought to liken it to a telephone line through which there is a constant flow of galvanic current and which can no longer be excited if that current ceases. Or better, let us imagine a widely-ramified electrical system for lighting and the transmission of motor power; what is expected of this system is that simple establishment of a contact shall be able to set any lamp or machine in operation. To make this possible, so that everything shall be ready to work, there must be a certain tension present throughout the entire network of lines of conduction, and the dynamo engine must expend a given quantity of energy for this purpose. In just the same way there is a certain amount of excitation present in the conductive paths of the brain when it is at rest but awake and prepared to work.¹

This view of the matter is supported by the fact that merely being awake, without doing any work, gives rise to fatigue and produces a need for sleep. The state of waking in itself causes a consumption of energy.

¹ I may perhaps venture here to indicate briefly the notion on which the above statements are based. We usually think of the sensory nerve cells as being passive receptive organs. This is a mistake. For the mere existence of a system of associative fibres proves that these sensory nerve-cells also send out excitation into the nerve-fibres. If excitation from two sensory cells flows into a nerve-fibre that connects them - whether *per continuitatem* or *per contiguitatem* - then a state of tension must exist in it. This state of tension has the same relation to the excitation flowing away in, for instance, a peripheral motor fibre as hydrostatic pressure has to the living force of flowing water or as electric tension has to an electric current. If all the nerve-cells are in a state of mean excitation and are exciting their nerve-processes, the whole immense network forms a single reservoir of 'nervous tension'. Apart then from a potential energy which lies quiescent in the chemical substance of the cell and an unknown form of kinetic energy which is discharged when the fibres are in a state of excitation, we must assume the existence of yet another quiescent state of nervous excitation: tonic excitation or nervous tension.

Let us imagine a man in a state of intense expectation, which is not, however, directed to any particular sensory field. We then have before us a brain which is quiescent but prepared for action. We may rightly suppose that in such a brain all the paths of conduction are at the maximum of their conductive capability - that they are in a state of tonic excitation. It is a significant fact that in ordinary language we speak of such a state as one of tension. Experience teaches us what a strain this state is and how fatiguing, though no actual motor or psychical work is performed in it.

This is an exceptional state, which, precisely on account of the great consumption of energy involved, cannot be tolerated for long. But even the normal state of being wide awake calls for an amount of intracerebral excitation varying between limits that are not very widely separated. Every diminishing degree of wakefulness down to drowsiness and true sleep is accompanied by correspondingly lower degrees of excitation.

When the brain is performing actual work, a greater consumption of energy is no doubt required than when it is merely *prepared* to perform work. (In just the same way the electrical system described above by way of comparison must cause a greater amount of electrical energy to flow into the conducting lines when a large number of lamps or motors are switched into the circuit.) Where functioning is normal no more energy is liberated than is immediately employed in activity. The brain, however, behaves like one of those electrical systems of restricted capability which are unable to produce both a large amount of light and of mechanical work at the same time. If it is transmitting power, only a little energy is available for lighting, and *vice versa*. Thus we find that if we are making great muscular efforts we are unable to engage in continuous thought, or that if we concentrate our attention in one sensory field the efficiency of the other cerebral origins is reduced - that is to say, we find that the brain works with a varying but limited amount of energy.

The non-uniform distribution of energy is no doubt determined by what Exner calls 'facilitation by attention' - by an increase in the conductive capability of the paths in use and a decrease in that of the others; and thus in a working brain the 'intracerebral tonic excitation', too, is non-uniformly distributed.¹

¹ The conception of the energy of the central nervous system as being a quantity distributed over the brain in a changing and fluctuating manner is an old one. 'La sensibilité', wrote Cabanis, 'semble se comporter à la manière d'une fluide dont la quantité totale est déterminée et qui, toutes les fois qu'il se jette en plus grande abondance dans un de ses canaux, diminue proportionnellement dans les autres.' (Quoted from Janet, 1894, 277.) ['Sensibility seems to behave like a fluid whose total quantity is fixed and which, whenever it pours into one of its channels in greater abundance, becomes proportionally less in the others.']

We wake up a person who is sleeping - that is, we suddenly raise the quantity of his tonic intracerebral excitation - by bringing a lively sensory stimulus to bear upon him. Whether alterations in the blood-circulation in the brain are essential links here in the causal chain, and whether the blood-vessels are directly dilated by the stimulus, or whether the dilatation is a consequence of the excitation of the cerebral elements - all this is undecided. What is certain is that the state of excitation, entering through a gateway of the senses, spreads over the brain from that point, becomes diffused and brings all the paths of conduction into a state of higher facilitation.

It is still not in the least clear, of course, how *spontaneous* awakening occurs - whether it is always one and the same portion of the brain that is the first to enter a state of waking excitation and the excitation then spreads from there, or whether sometimes one and sometimes another group of elements acts as the awakener. Nevertheless spontaneous awakening, which, as we know, can take place in complete quiet and darkness without any external stimulus, proves that the development of energy is based on the vital process of the cerebral elements themselves. A muscle remains unstimulated, quiescent, however long it has been in a state of rest and even though it has accumulated a maximum of tensile force. This is not so with the cerebral elements. We are no doubt right in supposing that during sleep the latter regain their previous condition and gather tensile force. When this has happened to a certain degree, when, as we may say, a certain level has been reached, the surplus flows away into the paths of conduction, facilitates them and sets up the intracerebral excitation of the waking state.

We can find an instructive example of the same thing in waking life. When the waking brain has been quiescent for a considerable time without transforming tensile force into live energy by functioning, there arises a need and an urge for activity. Long motor quiescence creates a need for movement (compare the aimless running round of a caged animal) and if this need cannot be satisfied a distressing feeling sets in. Lack of sensory stimuli, darkness and complete silence become a torture; mental repose, lack of perceptions, ideas and associative activity produce the torment of boredom. These unpleasurable feelings correspond to an 'excitement', to an increase in normal intracerebral excitation.

Thus the cerebral elements, after being completely restored liberate a certain amount of energy even when they are at rest and if this energy is not employed functionally it increases the normal intracerebral excitation. The result is a feeling of unpleasure. Such feelings are always generated when one of the organism's needs fails to find satisfaction. Since these feelings disappear when the surplus quantity of energy which has been liberated is employed functionally, we may conclude that the removal of such surplus excitation is a need of the organism. And here for the first time we meet the fact that there exists in the organism a '*tendency to keep intracerebral excitation constant*' (Freud).

Such a surplus of intracerebral excitation is a burden and a nuisance, and an urge to use it up arises in consequence. If it cannot be used in sensory or ideational activity, the surplus flows away in purposeless motor action, in walking up and down, and so on, and this we shall meet with later as the commonest method of discharging excessive tensions.

We are familiar with the great individual variations which are found in this respect: the great differences between lively people and inert and lethargic ones, between those who 'cannot sit still' and those who have an 'innate gift for lounging on sofas' and between mentally agile minds and dull ones which can tolerate intellectual rest for an unlimited length of time. These differences, which make up a man's 'natural temperament', are certainly based on profound differences in his nervous system - on the degree to which the functionally quiescent cerebral elements liberate energy.

We have spoken of a tendency on the part of the organism to keep tonic cerebral excitation constant. A tendency of this kind is, however, only intelligible if we can see what need it fulfils. We can understand the tendency in warm-blooded animals that to keep a constant mean temperature, because our experience has taught us that that temperature is an optimum for the functioning of their organs. And we make a similar assumption in regard to the constancy of the water-content of the blood; and so on. I think that we may also assume that there is an optimum for the height of the intracerebral tonic excitation. At that level of tonic excitation the brain is accessible to all external stimuli, the reflexes are facilitated, though only to the extent of normal reflex activity, and the store of ideas is capable of being aroused and open to association in the mutual relation between individual ideas which corresponds to a clear and reasonable state of mind. It is in this state that the organism is best prepared for work.

The situation is already altered by the uniform heightening of tonic excitation which constitutes 'expectation'. This makes the organism hyperaesthetic towards sensory stimuli, which quickly become distressing, and also increases its reflex excitability above what is useful (proneness to fright). No doubt this state is useful for some situations and purposes; but if it appears spontaneously and not for any such reasons, it does not improve our efficiency but impairs it. In ordinary life we call this being 'nervous'. In the great majority of forms of increase in excitation, however, the over-excitation is not uniform, and this is always detrimental to efficiency. We call this 'excitement'. That the organism should tend to maintain the optimum of excitation and to return to that optimum after it has been exceeded is not surprising, but quite in keeping with other regulating factors in the organism.

I shall venture once more to recur to my comparison with an electrical lighting system. The tension in the network of lines of conduction in such a system has an optimum too. If this is exceeded its functioning may easily be impaired; for instance, the electric light filaments may be quickly burned through. I shall speak later of the damage done to the system itself through a break-down of its insulation or through 'short-circuiting'.

(B)

Our speech, the outcome of the experience of many generations, distinguishes with admirable delicacy between those forms and degrees of heightening of excitation which are still useful for mental activity because they raise the free energy of all cerebral functions uniformly, and those forms and degrees which restrict that activity because they partly increase and partly inhibit these psychical functions in a manner that is *not* uniform. The first are given the name of 'incitement', and the second 'excitement'.¹ An interesting conversation, or a cup of tea or coffee has an 'inciting' effect; a dispute or a considerable dose of alcohol has an 'exciting' one. While incitement only arouses the urge to employ the increased excitation functionally, excitement seeks to discharge itself in more or less violent ways which are almost or even actually pathological. Excitement constitutes the psycho-physical basis of the effects, and these will be discussed below. But I must first touch briefly on some physiological and endogenous causes of increases of excitation.

Among these, in the first place, are the organism's major physiological needs and instincts: need for oxygen, craving for food, and thirst. Since the excitement which they set going is linked to certain sensations and purposive ideas, it is not such a pure example of increase of excitation as the one discussed above, which arose solely from the quiescence of the cerebral elements. The former always has its special colouring. But it is unmistakable in the anxious agitation which accompanies dyspnoea and in the restlessness of a starving man.

The increase of excitation that comes from these sources is determined by the chemical change in the cerebral elements themselves, which are short of oxygen, of tensile force or of water. It flows away along preformed motor paths, which lead to the satisfaction of the need that set it going: dyspnoea leads to breathing with effort, and hunger and thirst to a search for and attainment of food and water. The principle of the constancy of excitation scarcely comes into operation as far as this kind of excitation is concerned; for the interests which are served by the increase in excitation in these cases are of far greater importance to the organism than the re-establishment of normal conditions of functioning in the brain. It is true that we see animals in a zoo running backwards and forwards excitedly before feeding-time; but this may no doubt be regarded as a residue of the preformed motor activity of looking for food, which has now become useless owing to their being in captivity, and not as a means of freeing the nervous system of excitement.

If the chemical structure of the nervous system has been permanently altered by a persistent introduction of foreign substances, then a lack of these substances will cause states of excitation, just as the lack of normal nutritive substances does in healthy people. We see this in the excitement occurring in abstinence from narcotics.

¹ [In German '*Anregung*' = 'incitement', 'stimulation'; '*Aufregung*' = 'excitement', 'agitation'.]

A transition between these endogenous increases of excitation and the psychical affects in the narrower sense is provided by sexual excitation and sexual affect. Sexuality at puberty appears in the first of these forms, as a vague, indeterminate, purposeless heightening of excitation. As development proceeds, this endogenous heightening of excitation, determined by the functioning of the sex-glands, becomes firmly linked (in the normal course of things) with the perception or idea of the other sex - and, indeed, with the idea of a particular individual, where the remarkable phenomenon of falling in love occurs. This idea takes over the whole quantity of excitation liberated by the sexual instinct. It becomes an 'affective idea'; that is to say, when it is actively present in consciousness it sets going the increase of excitation which in point of fact originated from another source, namely the sex-glands.

The sexual instinct is undoubtedly the most powerful source of persisting increases of excitation (and consequently of neuroses). Such increases are distributed very unevenly over the nervous system. When they reach a considerable degree of intensity the train of ideas becomes disturbed and the relative value of the ideas is changed; and in orgasm thought is almost completely extinguished.

Perception too - the psychical interpretation of sense-impressions - is impaired. An animal which is normally timid and cautious becomes blind and deaf to danger. On the other hand, at least in males, there is an intensification of the aggressive instinct. Peaceable animals become dangerous until their excitation has been discharged in the motor activities of the sexual act.

(C)

A disturbance like this of the dynamic equilibrium of the nervous system - a non-uniform distribution of increased excitation - is what makes up the psychical side of affects.

No attempt will be made here to formulate either a psychology or a physiology of the affects. I shall only discuss a single point, which is of importance for pathology, and moreover only for ideogenic affects - those which are called up by perceptions and ideas. (Lange, 1885, has rightly pointed out that affects can be caused by toxic substances, or, as psychiatry teaches us, above all by pathological changes, almost in the same way as they can by ideas.)

It may be taken as self-evident that all the disturbances of mental equilibrium which we call acute affects go along with an increase of excitation. (In the case of *chronic* affects, such as sorrow and care, that is to say protracted anxiety, the complication is present of a state of severe fatigue which, though it maintains the non-uniform distribution of excitation, nevertheless reduces its height.) But this increased excitation cannot be employed in psychical activity. All powerful affects restrict association - the train of ideas. People become 'senseless' with anger or fright. Only the group of ideas which provoked the affect persists in consciousness, and it does so with extreme intensity. Thus the excitement cannot be levelled out by associative activity.

Affects that are 'active' or 'sthenic' do, however, level out the increased excitation by *motor* discharge. Shouting and jumping for joy, the increased muscular tone of anger, angry words and retaliatory deeds - all these allow the excitation to flow away in movements. Mental pain discharges it in difficult breathing and in an act of secretion: in sobs and tears. It is a matter of everyday experience that such reactions reduce excitement and allay it. As we have already remarked, ordinary language expresses this in such phrases as 'to cry oneself out', 'to blow off steam', etc. What is being got rid of is nothing else than the increased cerebral excitation.

Only some of these reactions, such as angry deeds and words, serve a purpose in the sense of making any change in the actual state of affairs. The rest serve no purpose whatever, or rather their only purpose is to level out the increase of excitation and to establish psychical equilibrium. In so far as they achieve this they serve the 'tendency to keep cerebral excitation constant'.

The 'asthenic' affects of fright and anxiety do not bring about this reactive discharge. Fright paralyses outright the power of movement as well as of association, and so does anxiety if the single useful reaction of running away is excluded by the cause of the affect of anxiety or by circumstances. The excitation of fright disappears only by a gradual levelling out.

Anger has adequate reactions corresponding to its cause. If these are not feasible, or if they are inhibited, they are replaced by substitutes. Even angry words are substitutes of this kind. But other, even quite purposeless, acts may appear as substitutes. When Bismarck had to suppress his angry feelings in the King's presence, he relieved himself afterwards by smashing a valuable vase on the floor. This deliberate replacement of one motor act by another corresponds exactly to the replacement of natural pain-reflexes by other muscular contractions. When a tooth is extracted the preformed reflex is to push away the dentist and utter a cry; if, instead of that, we contract the muscles of our arms and press against the sides of the chair, we are shifting the quantum of excitation that has been generated by the pain from one group of muscles to another. In the case of violent spontaneous toothache, where there is no preformed reflex apart from groaning, the excitation flows off in aimless pacing up and down. In the same way we transpose the excitation of anger from the adequate reaction to another one, and we feel relieved provided it is used up by *any* strong motor innervation.

If, however, the affect can find no discharge of excitation of any kind along these lines, then the situation is the same with anger as with fright and anxiety. The intracerebral excitation is powerfully increased, but is employed neither in associative nor in motor activity. In normal people the disturbance is gradually levelled out. But in some, abnormal reactions appear, An 'abnormal expression of the emotions', as Oppenheim says, is formed.

(3) HYSTERICAL CONVERSION

I shall scarcely be suspected of identifying nervous excitation with electricity, if I return once more to the comparison with an electrical system. If the tension in such a system becomes excessively high, there is danger of a break occurring at weak points in the insulation. Electrical phenomena then appear at abnormal points; or, if two wires lie close beside each other, there is a short circuit. Since a permanent change has been produced at these points, the disturbance thus brought about may constantly recur if the tension is sufficiently increased. An abnormal 'facilitation' has taken place.

That the conditions applying in the nervous system are to some extent similar can well be maintained. It forms throughout an interconnected whole; but at many points in it great, though not insurmountable, resistances are interposed, which prevent the general, uniform distribution of excitation. Thus in normal people in a waking state excitation in the organ of ideation does not pass over to the organs of perception: such people do not hallucinate. In the interests of the safety and efficiency of the organism, the nervous apparatuses of the complexes of organs which are of vital importance - the circulatory and digestive organs - are separated by strong resistances from the organs of ideation. Their independence is assured. They are not affected directly by ideas. But the resistances which prevent the passage of intracerebral excitation to the circulatory and digestive apparatuses vary in strength from one individual to another. All degrees of affective excitability are to be found between, on the one hand, the ideal (which is rarely met with to-day) of a man who is absolutely free from 'nerves', whose heart-action remains constant in every situation and is only affected by the particular work it has to perform, the man who has a good appetite and digestion, whatever danger he is in - between a man of this kind and, on the other hand, a 'nervous' man who has palpitations and diarrhoea on the smallest provocation.

However this may be, there are resistances in normal people against the passage of cerebral excitation to the vegetative organs. These resistances correspond to the insulation of electrical conducting lines. At points at which they are abnormally weak they are broken through when the tension of cerebral excitation is high, and this - the affective excitation - passes over to the peripheral organs. There ensues an 'abnormal expression of emotion'.

Of the two factors which we have mentioned as being responsible for this result, one has already been discussed by us in detail. This first factor is a high degree of intracerebral excitation which has failed to be levelled down either by ideational activities or by motor discharge, or which is too great to be dealt with in this way.

The second factor is an abnormal weakness of the resistances in particular paths of conduction. This may be determined by the individual's initial constitution (innate disposition); or it may be determined by states of excitation of long duration which, as one might say, loosen the whole structure of his nervous system and lower all its resistances (pubertal disposition); or it may be determined by weakening influences, such as illness and under-nourishment (disposition due to states of exhaustion). The resistance of particular paths of conduction may be lowered by a previous illness of the organ concerned which has facilitated the paths to and from the brain. A diseased heart is more susceptible to the influence of an affect than is a healthy one. 'I have a sounding-board in my abdomen', I was told by a woman who suffered from parametritis, 'if anything happens, it starts up my old pain.' (Disposition through local illness.)

The motor actions in which the excitation of affects is normally discharged are ordered and co-ordinated even though they are often useless. But an excessively strong excitation may by-pass or break through the co-ordinative centres and flow off in primitive movements. In infants, apart from the respiratory action of screaming, affects only produce and find expression in uncoordinated contractions of the muscles of this primitive kind - in arching the body and kicking about. As development proceeds, the musculature passes more and more under the control of the power of co-ordination and the will. But the opisthotonus, which represents the maximum of motor effort of the total somatic musculature, and the clonic movements of kicking and threshing about, persist throughout life as the form of reaction for the maximal excitation of the brain for the purely physical excitation in epileptic attacks as well as for the discharge of maximal affects in the shape of more or less epileptoid convulsions (viz. the purely motor part of hysterical attacks).

It is true that abnormal affective reactions of this kind are characteristic of hysteria. But they also occur apart from that illness. What they indicate is a more or less high degree of nervous disorder, not hysteria. Such phenomena cannot be described as hysterical if they appear as consequences of an affect which, though of great intensity, has an objective basis, but only if they appear with apparent spontaneity as manifestations of an illness. These latter, as many observations, including our own, have shown, are based on recollections which revive the original affect - or rather, *which would revive it if those reactions did not, in fact, occur instead.*

It may be taken for granted that a stream of ideas and recollections runs through the consciousness of any reasonably intelligent person while his mind is at rest. These ideas are so little vivid that they leave no trace behind in the memory and it is impossible afterwards to say how the associations occurred. If, however, an idea comes up that originally had a strong affect attached to it, that affect is revived with more or less intensity. The idea which is thus 'coloured' by affect emerges in consciousness clearly and vividly. The strength of the affect which can be released by a memory is very variable, according to the amount to which it has been exposed to 'wearing-away' by different influences, and especially according to the degree to which the original affect has been 'abreacted'. We pointed out in our 'Preliminary Communication' to what a varying extent the affect of anger at an insult, for instance, is called up by a recollection, according to whether the insult has been repaid or endured in silence. If the psychical reflex was fully achieved on the original occasion, the recollection of it releases a far smaller quantity of excitation.¹ If not, the recollection is perpetually forcing on to the subject's lips the abusive words which were originally suppressed and which would have been the psychical reflex to the original stimulus.

¹ The instinct of revenge, which is so powerful in the natural man and is disguised rather than repressed by civilization, is nothing whatever but the excitation of a reflex that has not been released. To defend oneself against injury in a fight and, in doing so, to injure one's opponent is the adequate and preformed psychical reflex. If it has been carried out insufficiently or not at all, it is constantly released again by recollection, and the 'instinct of revenge' comes into being as an irrational volitional impulse, just as do all other 'instincts'. The proof of this lies precisely in the irrationality of the impulse, its divorce from any question of usefulness or expediency, indeed in its disregard of all considerations of the subject's own safety. As soon as the reflex has been released, the irrational nature of the impulse can become conscious.

Ein andres Antlitz, eh sie geschehen,
Ein anderes zeigt die vollbrachte Tat.

[Literally: 'A deed shows one countenance before it has happened and another after it has been accomplished.']

If the original affect was discharged not in a normal but in an 'abnormal' reflex, this latter is equally released by recollection. The excitation arising from the affective idea is 'converted' (Freud) into a somatic phenomenon.

Should this abnormal reflex become completely facilitated by frequent repetition, it may, it seems, drain away the operative force of the releasing ideas so totally that the affect itself emerges to a minimal extent only, or not at all. In such a case the 'hysterical conversion' is complete. The idea, moreover, which now no longer produces any psychical consequences, may be overlooked by the subject, or may be promptly forgotten if it emerges, like any other idea which is unaccompanied by affect.

It may be easier to accept the possibility of a cerebral excitation which should have given rise to an idea being replaced in this way by an excitation of some peripheral path, if we call to mind the inverse course of events which follows when a preformed reflex fails to occur. I will select an extremely trivial example - the sneezing reflex. If a stimulus of the mucous membrane of the nose fails for any reason to release this preformed reflex, a feeling of excitation and tension arises, as we all know. The excitation, which has been unable to flow off along motor paths, now, inhibiting all other activity, spreads over the brain. This everyday example gives us the pattern of what happens when a psychical reflex, even the most complicated one, fails to occur. The excitement which we have discussed above as characteristic of the instinct of revenge is in essentials the same. And we can follow the same process even up to the highest regions of human achievement. Goethe did not feel he had dealt with an experience till he had discharged it in creative artistic activity. This was in his case the preformed reflex belonging to affects, and so long as it had not been carried out the distressing increase in his excitation persisted.

Intracerebral excitation and the excitatory process in peripheral paths are of reciprocal magnitudes: the former increases if and so long as no reflex is released; it diminishes and disappears when it has been transformed into peripheral nervous excitation. Thus it seems understandable that no observable affect is generated if the idea that should have given rise to it immediately releases an abnormal reflex into which the excitation flows away as soon as it is generated. The 'hysterical conversion' is then complete. The original intracerebral excitation belonging to the affect has been transformed into the excitatory process in the peripheral paths. What was originally an affective idea now no longer provokes the affect but only the abnormal reflex.¹

We have now gone a step beyond the 'abnormal expression of the emotions'. Hysterical phenomena (abnormal reflexes) do not seem to be ideogenic even to intelligent patients who are good observers, because the idea that gave rise to them is no longer coloured with affect and no longer marked out among other ideas and memories. They emerge as purely somatic phenomena, apparently without psychical roots.

¹ I am anxious not to drive the analogy with an electrical system to death. In view of the totally dissimilar conditions it can scarcely illustrate the processes in the nervous system, and can certainly not explain them. But I may once more recall the case in which, owing to excessively high tension, the insulation of the wires in a lighting system breaks down and a 'short circuit' occurs at some point in it. If electrical phenomena (such as overheating or sparking) occur at this point, the lamp to which the wire leads fails to light. In just the same way, the affect fails to appear if the excitation flows away in an abnormal reflex and is converted into a somatic phenomenon.

What is it that determines the discharge of affect in such a way that one particular abnormal reflex is produced rather than some other? Our observations answer this question in many instances by showing that here again the discharge follows the 'principle of least resistance' and takes place along those paths whose resistances have already been weakened by concurrent circumstances. This covers the case which we have already mentioned of a particular reflex being facilitated by already-existing somatic illness. If, for instance, someone suffers often from cardiac pains, these will also be provoked by affects. Alternatively, a reflex may be facilitated by the fact that the muscular innervation concerned was deliberately intended at the moment at which the affect originally occurred. Thus, Anna O. (in our first case history) tried, in her fright, to stretch out her right arm that had gone to sleep owing to pressure against the back of the chair, in order to ward off the snake; and from that time on the tetanus in her right arm was provoked by the sight of any snake-like object. Or again, in her emotion, she brought her eyes forcibly together in order to read the hands of the watch, and thereupon a convergent squint became one of the reflexes of that affect. And so on.

This is due to the operation of simultaneity, which, indeed, governs our normal associations. Every sense-perception calls back into consciousness any other sense-perception that appeared originally at the same time. (Cf. the text-book example of the visual image of a sheep and the sound of its bleating, etc.) If the original affect was accompanied by a vivid sense-impression, the latter is called up once more when the affect is repeated; and since it is a question of discharging excessively great excitation, the sense-impression emerges, not as a recollection, but as a hallucination. Almost all our case histories provide instances of this. It is also what happened in the case of a woman who experienced a painful affect at a time when she was having violent toothache due to periostitis, and who thenceforward suffered from infra-orbital neuralgia whenever the affect was renewed or even recollected.

What we have here is the facilitation of abnormal reflexes according to the general laws of association. But sometimes (though, it must be admitted, only in higher degrees of hysteria) true sequences of associated ideas lie between the affect and its reflex. Here we have *determination through symbolism*. What unites the affect and its reflex is often some ridiculous play upon words or associations by sound, but this only happens in dream-like states when the critical powers are low and lies outside the group of phenomena with which we are here dealing.

In a large number of cases the path taken by the train of determination remains unintelligible to us, because we often have a very incomplete insight into the patient's mental state and an imperfect knowledge of the ideas which were active at the time of the origin of the hysterical phenomenon. But we may assume that the process is not entirely unlike what we can observe clearly in more favourable cases.

The experiences which released the original affect, the excitation of which was then converted into a somatic phenomenon, are described by us as *psychical traumas*, and the pathological manifestation arising in this way, as *hysterical symptoms of traumatic origin*. (The term 'traumatic hysteria' has already been applied to phenomena which, as being consequences of physical injuries - traumas in the narrowest sense of the word - form part of the class of 'traumatic neuroses'.)

The genesis of hysterical phenomena that are determined by traumas finds a perfect analogy in the hysterical conversion of the psychical excitation which originates, not from external stimuli nor from the inhibition of normal psychical reflexes, but from the inhibition of the course of association. The simplest example and model of this is afforded by the excitation which arises when we cannot recollect a name or cannot solve a riddle, and so on. If someone tells us the name or gives us the answer to the riddle, the chain of associations is ended, and the excitation vanishes, just as it does on the ending of a reflex chain. The strength of the excitation caused by the blocking of a line of associations is in direct ratio to the interest which we take in them - that is, to the degree to which they set our will in motion. Since, however, the search for a solution of the problem, or whatever it may be, always involves a large amount of work, though it may be to no purpose, even a powerful excitation finds employment and does not press for discharge, and consequently never becomes pathogenic.

It does, however, become pathogenic if the course of associations is inhibited owing to ideas of equal importance being irreconcilable - if, for instance, fresh thoughts come into conflict with old-established ideational complexes. Such are the torments of religious doubt to which many people succumb and many more succumbed in the past. Even in such cases, however, the excitation and the accompanying psychical pain (the feeling of unpleasure) only reach any considerable height if some volitional interest of the subject's comes into play - if, for instance, a doubter feels himself threatened in the matter of his happiness or his salvation. Such a factor is always present, however, when the conflict is one between firmly-rooted complexes of moral ideas in which one has been brought up and the recollection of actions or merely thoughts of one's own, which are irreconcilable with them; when, in other words, one feels the pangs of conscience. The volitional interest in being pleased with one's own personality and satisfied with it comes into operation here and increases to the highest degree the excitation due to the inhibition of associations. It is a matter of everyday experience that a conflict like this between irreconcilable ideas has a pathogenic effect. What are mostly in question are ideas and processes connected with sexual life: masturbation in an adolescent with moral sensibilities; or, in a strictly conscientious married woman, becoming aware of an attraction to a man who is not her husband. Indeed, the first emergence of sexual feelings and ideas is very often in itself enough to bring about an intense state of excitation, owing to its conflicting with a deeply-rooted idea of moral purity.¹

A state of excitation of this kind is usually followed by psychical consequences, such as pathological depression and anxiety-states (Freud). Sometimes, however, concurrent circumstances bring about an abnormal somatic phenomenon in which the excitation is discharged. Thus there may be vomiting where the feeling of uncleanness produces a physical feeling of nausea, or a *tussis nervosa*, as in Anna O. (Case History 1), when moral anxiety provokes a spasm of the glottis, and so on.²

¹ Cf. on this point some interesting observations and comments by Benedikt.

² Compare a passage in Mach's 'Bewegungsempfindungen' which deserves to be recalled in this connection: 'It has often been found during the experiments (on giddiness) which I have described, that in general a feeling of nausea set in if it was difficult to bring the sensations of movement into harmony with the optical impressions. It appeared as though a part of the stimulus proceeding from the labyrinth had been compelled to leave the optic tracts, which were closed to it on account of another stimulus, and to enter upon quite other tracts . . . I have also repeatedly observed a feeling of nausea in making an attempt to combine stereoscopic images which are widely separated.'

Here we have nothing less than the physiological pattern for the generation of pathological, hysterical phenomena as a result of the co-existence of vivid ideas which are irreconcilable with one another.

There is a normal, appropriate reaction to excitation caused by very vivid and irreconcilable ideas - namely, to communicate them by speech. An amusingly exaggerated picture of the urge to do this is given in the story of Midas's barber, who spoke his secret aloud to the reeds. We meet the same urge as one of the basic factors of a major historical institution - the Roman Catholic confessional. Telling things is a relief; it discharges tension even when the person to whom they are told is not a priest and even when no absolution follows. If the excitation is denied this outlet it is sometimes converted into a somatic phenomenon, just as is the excitation belonging to traumatic affects. The whole group of hysterical phenomena that originate in this way may be described, with Freud, as *hysterical phenomena of retention*.

The account that we have hitherto given of the mechanism by which hysterical phenomena originate is open to the criticism that it is too schematic and simplifies the facts. In order that a healthy person who is not initially neuropathic may develop a genuine hysterical symptom, with its apparent independence of the mind and with a somatic existence in its own right, there must always be a number of concurrent circumstances.

The following case will serve as an example of the complicated nature of the process. A twelve-year-old boy, who had previously suffered from *pavor nocturnis* and whose father was highly neurotic, came home from school one day feeling unwell. He complained of difficulty in swallowing and headache. The family doctor assumed that the cause was a sore throat. But the condition did not improve even after several days. The boy refused food and vomited when it was pressed on him. He moved about listlessly, without energy or enjoyment; he wanted to lie in bed all the time and was very much run down physically. When I saw him five weeks later, he gave the impression of being a shy and shut-in child, and I became convinced that his condition had a psychical basis. On being questioned closely, he brought up a trivial explanation - a severe reproof given by his father - which had clearly not been the real cause of his illness. Nor could anything be learnt from his school. I promised that I would extract the information later under hypnosis. This, however, turned out to be unnecessary. In response to strong appeals from his clever and energetic mother, he burst into tears and told the following story. While he was on his way home from school he had gone into a urinal, and a man had held out his penis to him and asked him to take it into his mouth. He had run away in terror, and nothing else had happened to him. But he was ill from that instant. As soon as he had made his confession he recovered completely. - In order to produce the anorexia, the difficulty in swallowing and the vomiting, several factors were required: the boy's innate neurotic nature, his severe fright, the irruption of sexuality in its crudest form into his childish temperament and, as the specifically determining factor, the idea of disgust. The illness owed its persistence to the boy's silence, which prevented the excitation from finding its normal outlet.

In all other cases, as in this one, there must be a convergence of several factors before a hysterical symptom can be generated in anyone who has hitherto been normal. Such symptoms are invariably 'overdetermined', to use Freud's expression.

It may be assumed that an overdetermination of this sort is also present when the same affect has been called out by a series of several provoking causes. The patient and those about him attribute the hysterical symptom only to the last cause, though that cause has as a rule merely brought to light something that had already been almost accomplished by other traumas.

A girl of seventeen ¹ had her first hysterical attack (which was followed by a number of others) when a cat jumped on her shoulder in the dark. The attack seemed simply to be the result of fright. Closer investigation showed, however, that the girl, who was particularly good-looking and was not properly looked after, had recently had a number of more or less brutal attempts made on her, and had herself been sexually excited by them. (Here we have the factor of disposition.) A few days before, a young man had attacked her on the same dark staircase and she had escaped from him with difficulty. This was the actual psychical trauma, which the cat did no more than make manifest. But it is to be feared that in many such cases the cat is regarded as the *causa efficiens*.

In order for the repetition of an affect to bring about a conversion in this way, it is not always necessary that there should be a number of *external* provoking causes; the renewal of the affect in *memory* is often also enough, if the recollection is repeated rapidly and frequently, immediately after the trauma and before its affect has become weakened. This is enough if the affect was a very powerful one. Such is the case in traumatic hysteria, in the narrower sense of the word. During the days following a railway accident, for instance, the subject will live through his frightful experiences again both in sleeping and waking, and always with the renewed affect of fright, till at last, after this period of 'psychical working-out [*élaboration*]' (in Charcot's phrase) or of 'incubation', conversion into a somatic phenomenon takes place. (Though there is another factor concerned which we shall have to discuss later.)

As a rule, however, an affective idea is promptly subjected to 'wearing away', to all the influences touched on in our 'Preliminary Communication', which deprive it little by little of its quota of affect. Its revival causes an ever-diminishing amount of excitation, and the recollection thus loses the capacity to contribute to the production of a somatic phenomenon. The facilitation of the abnormal reflex disappears and the *status quo ante* is thereupon re-established.

¹ I have to thank Herr Assistent Dr. Paul Karplus for this case.

The 'wearing-away' influences, however, are all of them effects of association, of thinking, of corrections by reference to other ideas. This process of correction becomes impossible if the affective idea is withdrawn from 'associative contact'. When this happens the idea retains its whole quota of affect. Since at every renewal the whole sum of excitation of the original affect is liberated once more, the facilitation of the abnormal reflex that was started at the time is finally completed; or, if the facilitation was already complete, it is maintained and stabilized. The phenomenon of hysterical conversion is in this way permanently established.

Our observations show two ways in which affective ideas can be excluded from association.

The first is 'defence', the deliberate suppression of distressing ideas which seem to the subject to threaten his happiness or his self-esteem. In his paper on 'The Neuro-Psychoses of Defence' (1894a) and in his case histories in the present volume, Freud has discussed this process, which undoubtedly possesses very high pathological significance. We cannot, it is true, understand how an idea can be deliberately repressed from consciousness. But we are perfectly familiar with the corresponding positive process, that of concentrating attention on an idea, and we are just as unable to say how we effect *that*. Ideas, then, from which consciousness is diverted, which are not thought about, are also withdrawn from the wearing-away process and retain their quota of affect undiminished.

We have further found that there is another kind of idea that remains exempt from being worn away by thought. This may happen, not because one does not *want* to remember the idea, but because one *cannot* remember it: because it originally emerged and was endowed with affect in states in respect of which there is amnesia in waking consciousness - that is, in hypnosis or in states similar to it. The latter seem to be of the highest importance for the theory of hysteria, and accordingly deserve a somewhat fuller examination.¹

¹ When, here and later on, we speak of ideas that are currently present and operative but yet unconscious, we are seldom concerned with *single* ideas (such as the big snake hallucinated by Anna O. which started her contracture). It is almost always a question of *complexes* of ideas, of recollections of external events and trains of thought of the subject's own. It may sometimes happen that every one of the individual ideas comprised in such a complex of ideas is thought of consciously, and that what is exiled from consciousness is only the particular combination of them.

(4) HYPNOID STATES

When, in our 'Preliminary Communication' we put forward the thesis that the basis and *sine qua non* of hysteria is the existence of hypnoid states, we were overlooking the fact that Moebius had already said exactly the same thing in 1890. 'The necessary condition for the (pathogenic) operation of ideas is, on the one hand, an innate - that is, hysterical - disposition and, on the other, a special frame of mind. We can only form an imprecise idea of this frame of mind. It must resemble a state of hypnosis; it must correspond to some kind of vacancy of consciousness in which an emerging idea meets with no resistance from any other - in which, so to speak, the field is clear for the first comer. We know that a state of this kind can be brought about not only by hypnotism but by emotional shock (fright, anger, etc.) and by exhausting factors (sleeplessness, hunger, and so on).'

The problem to whose solution Moebius was here making a tentative approach is that of the generating of somatic phenomena by ideas. He here recalls the ease with which this can occur under hypnosis, and regards the operation of affects as analogous. Our own, somewhat different, view on the operation of the affects has been fully explained above. I need not, therefore, enter further into the difficulty involved in Moebius's assumption that in anger there is a 'vacancy of consciousness'¹ (which admittedly exists in fright and prolonged anxiety) or into the more general difficulty of drawing an analogy between the state of excitation in an affect and the quiescent state in hypnosis. We shall come back later, however, to these remarks by Moebius, which in my opinion embody an important truth.

¹ It is possible that by this description Moebius means nothing else than the inhibition of the current of ideas - an inhibition which certainly occurs in the case of affects, though owing to entirely different causes from those operating in hypnosis.

For us, the importance of these states which resemble hypnosis - 'hypnoid' states - lies, in addition and most especially, in the amnesia that accompanies them and in their power to bring about the splitting of the mind which we shall discuss presently and which is of fundamental significance for 'major hysteria'. We still attribute this importance to hypnoid states. But I must add a substantial qualification to our thesis. Conversion - the ideogenic production of somatic phenomena - can also come about apart from hypnoid states. Freud has found in the deliberate amnesia of defence a second source, independent of hypnoid states, for the construction of ideational complexes which are excluded from associative contact. But, accepting this qualification, I am still of opinion that hypnoid states are the cause and necessary condition of many, indeed of most, major and complex hysterias.

First and foremost, of course, among hypnoid states are to be numbered true auto-hypnoses, which are distinguished from artificial hypnoses only by the fact of their originating spontaneously. We find them in a number of fully-developed hysterias, occurring with varying frequency and duration, and often alternating rapidly with normal waking states (cf. Case Histories 1 and 2). On account of the dream-like nature of their content, they often deserve the name of '*delirium hysterikum*'. What happens during auto-hypnotic states is subject to more or less total amnesia in waking life (whereas it is completely remembered in artificial hypnosis). The amnesia withdraws the psychical products of these states, the associations that have been formed in them, from any correction during waking thought; and since in auto-hypnosis criticism and supervision by reference to other ideas is diminished, and, as a rule, disappears almost completely, the wildest delusions may arise from it and remain untouched for long periods. Thus it is almost only in these states that there arises a somewhat complicated irrational 'symbolic relation between the precipitating cause and the pathological phenomenon', which, indeed, is often based on the most absurd similarities of sound and verbal associations. The absence of criticism in auto-hypnotic states is the reason why auto-suggestions so frequently arise from them as, for instance, when a paralysis remains behind after a hysterical attack. But, and this may be merely by chance, we have scarcely ever in our analyses come across an instance of a hysterical phenomenon originating in this manner. We have always found it happen, in auto-hypnosis no less than outside it, as a result of the same process - namely, conversion of an affective excitation.

In any case, this 'hysterical conversion' takes place more easily in auto-hypnosis than in the waking state, just as suggested ideas are realized physically as hallucinations and movements so much more easily in artificial hypnosis. Nevertheless the process of conversion of excitation is essentially the same as has been described above. When once it has taken place, the somatic phenomenon is repeated if the affect and the auto-hypnosis occur simultaneously. And in that case it seems as though the hypnotic state has been called up by the affect itself. Accordingly, so long as there is a clear-cut alternation between hypnosis and full waking life, the hysterical symptom remains restricted to the hypnotic state and is strengthened there by repetition; moreover, the idea that gave rise to it is exempt from correction by waking thoughts and their criticism precisely because it never emerges in clear waking life.

Thus with Anna O. (Case History 1) the contracture of her right arm, which was associated in her auto-hypnosis with the affect of anxiety and the idea of the snake, remained for four months restricted to the moments during which she was in a hypnotic state (or, if we consider this term inappropriate for *absences* of very short duration, a hypnoid one), though it recurred frequently. The same thing happened with other conversions that were carried out in her hypnoid state; and in this way the great complex of hysterical phenomena grew up in a condition of complete latency and came into the open when her hypnoid state became permanent.

The phenomena which have arisen in this way emerge into clear consciousness only when the split in the mind, which shall discuss later, has been completed, and when the alternation between waking and hypnoid states has been replaced by co-existence between the normal and the hypnoid complexes of ideas.

Are hypnoid states of this kind in existence before the patient falls ill, and how do they come about? I can say very little about this, for apart from the case of Anna O. we have no observations at our disposal which might throw light on the point. It seems certain that with her the auto-hypnosis had the way paved for it by habitual reveries and that it was fully established by an affect of protracted anxiety, which, indeed, would itself be the basis for a hypnoid state. It seems not improbable that this process holds good fairly generally.

A great variety of states lead to 'absence of mind' but only a few of them predispose to auto-hypnosis or pass over immediately into it. An investigator who is deep in a problem is also no doubt anaesthetic to a certain degree, and he has large groups of sensations of which he forms no conscious perception; and the same is true of anyone who is using his creative imagination actively (cf. Anna O.'s 'private theatre'). But in such states energetic mental work is carried on, and the excitation of the nervous system which is liberated is used up in this work. In states of abstraction and dreaminess, on the other hand, intracerebral excitation sinks below its clear waking level. These states border on sleepiness and pass over into sleep. If during such a state of absorption, and while the flow of ideas is inhibited, a group of affectively-coloured ideas is active, it creates a high level of intracerebral excitation which is not used up by mental work and is at the disposal of abnormal functioning, such as conversion.

Thus neither 'absence of mind' during energetic work nor unemotional twilight states are pathogenic; on the other hand, reveries that are filled with emotion and states of fatigue arising from protracted affects *are* pathogenic. The broodings of a care-ridden man, the anxiety of a person watching at the sick-bed of someone dear to him, the day-dreams of a lover - these are states of this second kind. Concentration on the affective group of ideas begins by producing 'absence of mind'. The flow of ideas grows gradually slower and at last almost stagnates; but the affective idea and its affect remain active, and so consequently does the great quantity of excitation which is not being used up functionally. The similarity between this situation and the determinants of hypnosis seems unmistakable. The subject who is to be hypnotized must not really go to sleep, that is to say, his intracerebral excitation must not sink to the level of sleep; but his flow of ideas must be inhibited. When this is so, the whole mass of excitation is at the disposal of the suggested idea.

This is the way in which pathogenic auto-hypnosis would seem to come about in some people - by affect being introduced into a habitual reverie. This is perhaps one of the reasons why in the anamnesis of hysteria we so often come across the two great pathogenic factors of being in love and sick-nursing. In the former, the subject's longing thoughts about his absent loved one create in him a 'rapt' state of mind, cause his real environment to grow dim, and then bring his thinking to a standstill charged with affect; while in sick-nursing the quiet by which the subject is surrounded, his concentration on an object, his attention fixed on the patient's breathing - all this sets up precisely the conditions demanded by many hypnotic procedures and fills the twilight state produced in this way with the affect of anxiety. It is possible that these states differ only quantitatively from true auto-hypnoses and that they pass over into them.

Once this has happened, the hypnosis-like state is repeated again and again when the same circumstances arise; and the subject, instead of the normal *two* conditions of mind, has three: waking, sleeping and the hypnoid state. We find the same thing happening when deep artificial hypnosis has been frequently brought on.

I cannot say whether spontaneous hypnotic states may also be generated without an affect intervening in this way, as a result of an innate disposition; but I consider it very probable. When we see the difference in susceptibility to artificial hypnosis both among healthy and sick people and how easily it is brought on in some, it seems reasonable to suppose that in such people it can also appear spontaneously. And a disposition for this is perhaps necessary before a reverie can turn into an auto-hypnosis. I am therefore far from attributing to all hysterical patients the generating mechanism which we have been taught by Anna O.

I speak of hypnoid states rather than of hypnosis itself because it is so difficult to make a clear demarcation of these states, which play such an important part in the genesis of hysteria. We do not know whether reveries, which were described above as preliminary stages of auto-hypnosis, may not themselves be able to produce the same pathological effect as auto-hypnosis, and whether the same may not also be true of a protracted affect of anxiety. It is certainly true of fright. Since fright inhibits the flow of ideas at the same time at which an affective idea (of danger) is very active, it offers a complete parallel to a reverie charged with affect; and since the recollection of the affective idea, which is constantly being renewed, keeps on re-establishing this state of mind, 'hypnoid fright' comes into being, in which conversion is either brought about or stabilized. Here we have the incubation stage of 'traumatic hysteria' in the strict sense of the words.

In view of the fact that states of mind which are so different though they agree with one another in the most important respect can be classed with auto-hypnosis, it seems desirable to adopt the expression 'hypnoid', which lays stress on this internal similarity. It sums up the view put forward by Moebius in the passage quoted above. Most of all, however, it points to auto-hypnosis itself, the importance of which in the genesis of hysterical phenomena rests on the fact that it makes conversion easier and protects (by amnesia) the converted ideas from wearing-away - a protection which leads, ultimately, to an increase in the psychical splitting.

If a somatic symptom is caused by an idea and is repeatedly set going by it, we should expect that intelligent patients capable of self-observation would be conscious of the connection; they would know by experience that the somatic phenomenon appeared at the same time as the memory of a particular event. The underlying causal nexus is, it is true, unknown to them; but all of us always know what the idea is which makes us cry or laugh or blush, even though we have not the slightest understanding of the nervous mechanism of these ideogenic phenomena. Sometimes patients do really observe the connection and are conscious of it. For instance, a woman may say that her mild hysterical attack (trembling and palpitations, perhaps) comes from some great emotional disturbance and is repeated when, and only when, some event reminds her of it. But this is not the case with very many or indeed the majority of hysterical symptoms. Even intelligent patients are unaware that their symptoms arise as the result of an idea and regard them as physical phenomena on their own account. If it were otherwise the psychical theory of hysteria must already have reached a respectable age.

It would be plausible to believe that, though the symptoms in question were ideogenic in the first instance, the repetition of them has, to use Romberg's phrase, 'imprinted' them into the body, and they would now no longer be based on a psychical process but on modifications in the nervous system which have occurred in the meantime: they would have become self-sufficient, genuinely somatic symptoms.

This view is in itself neither untenable nor improbable. But I believe that the new light which our observations have thrown on the theory of hysteria lies precisely in its having shown that this view is inadequate to meet the facts, at any rate in many instances. We have seen that hysterical symptoms of the most various kinds which have lasted for many years 'immediately and permanently disappeared when we had succeeded in bringing clearly to light the memory of the event by which they were provoked and in arousing their accompanying affect, and when the patient had described that event in the greatest possible detail and had put the affect into words'. The case histories which have been reported in these pages provide some pieces of evidence in support of these assertions. 'We may reverse the dictum "*cessante causa cessat effectus*" ["when the cause ceases the effect ceases"], and conclude from these observations that the determining process' (that is, the recollection of it) 'continues to operate for years - not indirectly, through a chain of intermediate causal links, but as a *directly* releasing cause - just as a psychical pain that is remembered in waking consciousness still provokes a lachrymal secretion long after the event. Hysterics suffer mainly from reminiscences.' But if this is so - if the memory of the psychical trauma must be regarded as operating as a contemporary agent, like a foreign body, long after its forcible entrance, and if nevertheless the patient has no consciousness of such memories or their emergence - then we must admit that *unconscious ideas exist and are operative*.

Moreover, when we come to analyse hysterical phenomena we do not only find such unconscious ideas *in isolation*. We must recognize the fact that in reality, as has been shown by the valuable work carried out by French investigators, large complexes of ideas and involved psychical processes with important consequences remain completely unconscious in a number of patients and co-exist with conscious mental life; we must recognize that there is such a thing as a splitting of psychical activity, and that this is of fundamental value for our understanding of complicated hysterias.

I may perhaps be allowed to explore this difficult and obscure region rather more fully. The need to establish the meaning of the terminology that has been used may to some extent excuse the theoretical discussion which follows.

(5) UNCONSCIOUS IDEAS AND IDEAS INADMISSIBLE TO CONSCIOUSNESS -
SPLITTING OF THE MIND

We call those ideas conscious which we are aware of. There exists in human beings the strange fact of self-consciousness. We are able to view and observe, as though they were objects, ideas that emerge in us and succeed one another. This does not happen always, since occasions for self-observation are rare. But the capacity for it is present in everyone, for everyone can say: 'I thought this or that.' We describe as conscious those ideas which we observe as active in us, or which we should so observe if we attended to them. At any given moment of time there are very few of them; and if others, apart from those, should be current at the time, we should have to call them *unconscious* ideas.

It hardly seems necessary any longer to argue in favour of the existence of current ideas that are unconscious or subconscious. They are among the commonest facts of everyday life. If I have forgotten to make one of my medical visits, I have feelings of lively unrest. I know from experience what this feeling means: that I have forgotten something. I search my memories in vain; I fail to discover the cause, till suddenly, hours later perhaps, it enters my consciousness. But I have been uneasy the whole time. Accordingly, the idea of the visit has been all the time operative, that is to say present, but not in my consciousness. Or again, a busy man may have been annoyed by something one morning. He is entirely absorbed by his office work; while he is doing it his conscious thoughts are fully occupied, and he gives no thought to his annoyance. But his decisions are influenced by it and he may well say 'no' where he would otherwise have said 'yes'. So in spite of everything this memory is operative, that is to say present. A great deal of what we describe as 'mood' comes from sources of this kind, from ideas that exist and are operative beneath the threshold of consciousness. Indeed, the whole conduct of our life is constantly influenced by subconscious ideas. We can see every day how, where there is mental degeneration, as for instance in the initial stages of general paralysis, the inhibitions which normally restrain certain actions become weaker and disappear. But the patient who now makes indecent jokes in the presence of women was not, in his healthy days, prevented from doing so by conscious memories and reflections; he avoided it 'instinctively' and 'automatically' - that is to say, he was restrained by ideas which were called up by the impulse to behave in this way, but which remained beneath the threshold of consciousness, though they nevertheless inhibited the impulse. All intuitive activity is directed by ideas which are to a large extent subconscious. For only the clearest and most intense ideas are perceived by self-consciousness, whilst the great mass of current but weaker ideas remains unconscious.

The objections that are raised against 'unconscious ideas' existing and being operative seem for the most part to be juggling with words. No doubt 'idea' is a word belonging to the terminology of conscious thinking, and 'unconscious idea' is therefore a self-contradictory expression. But the physical process which underlies an idea is the same in content and form (though not in quantity) whether the idea rises above the threshold of consciousness or remains beneath it. It would only be necessary to construct some such term as 'ideational substratum' in order to avoid the contradiction and to counter the objection.

Thus there seems to be no theoretical difficulty in also recognizing unconscious ideas as causes of pathological phenomena. But if we go into the matter more closely we come upon other difficulties. As a rule, when the intensity of an unconscious idea increases it enters consciousness *ipso facto*. Only when its intensity is slight does it remain unconscious. What seems hard to understand is how an idea can be sufficiently intense to provoke a lively motor act, for instance, and at the same time not intense enough to become conscious.

I have already mentioned a view which should not, perhaps, be dismissed out of hand. On this view the clarity of our ideas, and consequently their capacity for being observed by our self-consciousness - that is, for being conscious - is determined, among other things, by the feelings of pleasure or displeasure which they arouse, by their quota of affect. When an idea immediately produces lively somatic consequences, this implies that the excitation engendered by it flows off into the paths concerned in these consequences, instead of, as would happen otherwise, becoming diffused in the brain; and precisely *because* this idea has physical consequences, because its sums of psychical stimuli have been 'converted' into somatic ones, it loses the clarity which would otherwise have marked it out in the stream of ideas. Instead of this it is lost among the rest.

Suppose, for instance, that someone has had a violent affect during a meal and has not 'abreacted' it. When subsequently he attempts to eat he is overtaken by choking and vomiting and these seem to him purely somatic symptoms. His hysterical vomiting continues for some considerable time. It disappears after the affect has been revived, described and reacted to under hypnosis. There can be no doubt that every attempt to eat called up the memory concerned. This memory started the vomiting but did not appear clearly in consciousness, because it was now without affect, whereas the vomiting absorbed the attention completely.

It is conceivable that the reason which has just been given explains why *some* ideas that release hysterical phenomena are not recognized as their causes. But this reason - the fact that ideas that have lost their affect because they have been converted are overlooked - cannot possibly explain why, in other cases, ideational complexes that are anything but devoid of affect do not enter consciousness. Numerous examples of this are to be found in our case histories.

In patients like these we found that it was the rule for the emotional disturbance - apprehensiveness, angry irritability, grief - to precede the appearance of the somatic symptom or to follow it immediately, and to increase, either until it was cleared up by being given utterance in words or until the affect and the somatic phenomenon gradually disappeared again. Where the former happened the quality of the affect always became quite understandable, even though its intensity could not fail to seem to a normal person (and to the patient himself, after it had been cleared up) to be out of all proportion. These, then, were ideas which were intense enough not merely to cause powerful somatic phenomena but also to call out the appropriate affect and to influence the course of association by bringing allied ideas into prominence - but which, in spite of all this, remained outside consciousness themselves. In order to bring them into consciousness hypnosis was necessary (as in Case Histories 1 and 2), or (as in Case Histories 4 and 5) a laborious search had to be made with strenuous help from the physician.

Ideas such as these which, though current, are unconscious, not because of their relatively small degree of liveliness, but in spite of their great intensity, may be described as ideas that are 'inadmissible to consciousness'.¹

The existence of ideas of this kind that are inadmissible to consciousness is pathological. In normal people all ideas that can become current at all enter consciousness as well if they are sufficiently intense. In our patients we find a large complex of ideas that are admissible to consciousness existing side by side with a smaller complex of ideas that are not. Thus in them the field of ideational psychical activity does not coincide with potential consciousness. The latter is more restricted than the former. Their psychical ideational activity is divided into a conscious and an unconscious part, and their ideas are divided into some that are admissible and some that are inadmissible to consciousness. We cannot, therefore, speak of a splitting of consciousness, though we can of a *splitting of the mind*.

Conversely, these subconscious ideas cannot be influenced or corrected by conscious thought. They are very often concerned with experiences which have in the meantime lost their meaning - dread of events which did not occur, fright that turned to laughter or joy after a rescue. Such subsequent developments deprive the memory of all its affect so far as consciousness is concerned; but they leave the subconscious idea, which provokes somatic phenomena, completely untouched.

¹ This expression [*Bewusstseinsunfähig*] is not unambiguous and for that reason leaves much to be desired. It is, however, constructed on the analogy of '*Hoffähig*' ['admissible to Court', 'having the *entrée*'] and may in the meantime be used for lack of a better term.

Perhaps I may be allowed to quote another example. A young married woman was for some time very much worried about her younger sister's future. As a result of this her period, normally regular, lasted for two weeks; she was tender in the left hypogastrium, and twice she found herself lying stiff on the floor, coming out of a 'faint'. There followed an ovarian neuralgia on the left side, with signs of a severe peritonitis. The absence of fever, and a contracture of the left leg (and of her back), showed that the illness was a *pseudo*-peritonitis; and when, a few years later, the patient died and an autopsy was performed, all that was found was a 'microcystic degeneration' of *both* ovaries without any traces of an old peritonitis. The severe symptoms disappeared by degrees and left behind an ovarian neuralgia, a contracture of the muscles of the back, so that her trunk was as stiff as a board, and a contracture of the left leg. The latter was got rid of under hypnosis by direct suggestion. The contracture of her back was unaffected by this. Meanwhile her younger sister's difficulties had been completely smoothed out and all her fears on that score had vanished. But the hysterical phenomena, which could only have been derived from them, persisted unaltered. It was tempting to suppose that what we were faced by were changes in innervation, which had assumed an independent status and were no longer attached to the idea that had caused them. But after the patient had been compelled under hypnosis to tell the whole story up to the time when she had fallen ill of 'peritonitis' - which she did most unwillingly - she immediately sat up in bed without assistance, and the contracture of her back disappeared for ever. (Her ovarian neuralgia, which was undoubtedly much older in its origin, remained unaffected.) Thus we see that her pathogenic anxious idea had persisted in active operation for months on end, and that it had been completely inaccessible to any correction by actual events.

If we are obliged to recognize the existence of ideational complexes that never enter consciousness and are not influenced by conscious thought, we shall have admitted that, even in such simple cases of hysteria as the one I have just described, there is a splitting of the mind into two relatively independent portions. I do not assert that everything that we call hysterical has a splitting of this kind as its basis and necessary condition; but I *do* assert that 'the splitting of psychical activity which is so striking in the well-known cases in the form of "*double conscience*" is present to a rudimentary degree in every major hysteria', and that 'the liability and tendency to such a dissociation is the basic phenomenon of this neurosis'.

But before entering into a discussion of this subject, I must add a comment with regard to the unconscious ideas which produce somatic effects. Many hysterical phenomena last continuously for a long time, like the contracture in the case described above. Should we and may we suppose that during all this time the causative idea is perpetually active and currently present? I think so. It is true that in healthy people we see their psychical activity going forward to the accompaniment of a rapid change of ideas. But we find sufferers from severe melancholia immersed continuously for long periods in the same distressing idea which is perpetually active and present. Indeed, we may well believe that even when a healthy person has a great care on his mind it is present all the time, since it governs his facial expression even when his consciousness is filled with other thoughts. But the portion of psychical activity which is separated off in hysterical subjects and which we think of as filled with unconscious ideas contains as a rule such a meagre store of them and is so inaccessible to interchange with external impressions that it is easy to believe that a single idea can be permanently active in it.

If it seems to us, as it does to Binet and Janet, that what lies at the centre of hysteria is a splitting off of a portion of psychical activity, it is our duty to be as clear as possible on this subject. It is only too easy to fall into a habit of thought which assumes that every substantive has a substance behind it - which gradually comes to regard 'consciousness' as standing for some actual thing; and when we have become accustomed to make use metaphorically of spatial relations, as in the term 'sub-consciousness', we find as time goes on that we have actually formed an idea which has lost its metaphorical nature and which we can manipulate easily as though it was real. Our mythology is then complete.

All our thinking tends to be accompanied and aided by spatial ideas, and we talk in spatial metaphors. Thus when we speak of ideas which are found in the region of clear consciousness and of unconscious ones which never enter the full light of self-consciousness, we almost inevitably form pictures of a tree with its trunk in daylight and its roots in darkness, or of a building with its dark underground cellars. If, however, we constantly bear in mind that all such spatial relations are metaphorical and do not allow ourselves to be misled into supposing that these relations are literally present in the brain, we may nevertheless speak of a consciousness and a subconsciousness. But only on this condition.

We shall be safe from the danger of allowing ourselves to be tricked by our own figures of speech if we always remember that after all it is in the same brain, and most probably in the same cerebral cortex, that conscious and unconscious ideas alike have their origin. How this is possible we cannot say. But then we know so little of the psychical activity of the cerebral cortex that one puzzling complication the more scarcely increases our limitless ignorance. We must take it as a fact that in hysterical patients a part of their psychical activity is inaccessible to perception by the self-consciousness of the waking individual and that their mind is thus split.

A universally known example of a division of psychical activity like this is to be seen in hysterical attacks in some of their forms and stages. At their beginning, conscious thought is often extinguished; but afterwards it gradually awakens. Many intelligent patients admit that their conscious ego was quite lucid during the attack and looked on with curiosity and surprise at all the mad things they did and said. Such patients have, furthermore, the (erroneous) belief that with a little goodwill they could have inhibited the attack, and they are inclined to blame themselves for it. 'They need not have behaved like that.' (Their self-reproaches of being guilty of simulation are also to a great extent based on this feeling.) But when the next attack comes on, the conscious ego is as little able to control what happens as in earlier ones. - Here we have a situation in which the thought and ideation of the conscious waking ego stands alongside of the ideas which normally reside in the darkness of the unconscious but which have now gained control over the muscular apparatus and over speech, and indeed even over a large part of ideational activity itself: the splitting of the mind is manifest.

It may be remarked that the findings of Binet and Janet deserve to be described as a splitting not merely of psychical activity but of consciousness. As we know, these observers have succeeded in getting into contact with their patients' 'subconsciousness', with the portion of psychical activity of which the conscious waking ego knows nothing; and they have been able in some of their cases to demonstrate the presence of all the psychical functions, including self-consciousness, in that portion, since it has access to the memory of earlier psychical events. This half of a mind is therefore quite complete and conscious in itself. In our cases the part of the mind which is split off is 'thrust into darkness', as the Titans are imprisoned in the crater of Etna, and can shake the earth but can never emerge into the light of day. In Janet's cases the division of the realm of the mind has been a total one. Nevertheless, there is still inequality in status. But this, too, disappears when the two halves of consciousness alternate, as they do in the well known cases of '*double conscience*', and when they do not differ in their functional capability.

But let us return to the ideas which we have shown in our patients as the causes of their hysterical phenomena. It is far from being possible for us simply to describe them all as being 'unconscious' and 'inadmissible to consciousness'. They form an almost unbroken scale, passing through every gradation of vagueness and obscurity, between perfectly conscious ideas which release an unusual reflex and those which never enter consciousness in waking life but only in hypnosis. In spite of this, we regard it as established that a splitting of psychical activity occurs in the more severe degrees of hysteria and that it alone seems to make a psychical theory of the illness possible.

What, then, can be asserted or suspected with probability about the causes and origin of this phenomenon?

Janet, to whom the theory of hysteria owes so very much and with whom we are in agreement in most respects, has expressed a view on this point which we are unable to accept.

Janet's view is the following. He considers that the 'splitting of a personality' rests on an innate psychological weakness ('*insuffisance psychologique*'). All normal mental activity presupposes a certain capacity for 'synthesis', the ability to unite several ideas into a complex. The combination of the various sense-perceptions into a picture of the environment is already a synthetic activity of this kind. This mental function is found to be far below the normal in hysterical patients. If a normal person's attention is directed as fully as possible upon some point, e. g. upon a perception by a single sense, it is true that he temporarily loses the capacity to apperceive impressions from the other senses - that is, to take them up into his conscious thought. But in hysterical subjects this happens without any special concentration of the attention. As soon as they perceive anything they are inaccessible to other sense-perceptions. Indeed, they are not even in a position to take in together a number of impressions coming from a *single* sense. They can, for instance, only apperceive tactile sensations in one half of the body; those from the other side reach the centre and are used for the co-ordination of movement, but are not apperceived. A person like this is hemi-anaesthetic. In normal people, an idea calls into consciousness a great number of others by association; these may be related to the first one, for instance, in a confirmatory or an inhibiting manner, and only the most vivid ideas are so extremely powerful that their associations remain below the threshold of consciousness. In hysterical people this is always the case. Every idea takes possession of the whole of their limited mental activity, and this accounts for their excessive affectivity. This characteristic of their mind is described by Janet as the 'restriction of the field of consciousness' of hysterical patients, on the analogy of a 'restriction of the field of vision'. For the most part the sense-impressions that are not apperceived and the ideas that are aroused but do not enter consciousness cease without producing further consequences. Sometimes, however, they accumulate and form complexes - mental strata withdrawn from consciousness; they form a subconsciousness. Hysteria, which is essentially based on this splitting of the mind, is a '*maladie par faiblesse*' ['disease due to weakness'], and that is why it develops most readily when a mind which is innately weak is submitted to influences that weaken it still further or is faced by heavy demands in relation to which its weakness stands out still more.

Janet's opinions, as thus summarized, already give his answer to the important question as to the disposition to hysteria - as to the nature of the *typus hystericus* (taking the term in the sense in which we speak of a *typus phthisicus*, by which we understand the long narrow thorax, the small heart, etc.). Janet regards a particular form of congenital mental weakness as the disposition to hysteria. In reply, we should like to formulate our own view briefly as follows. It is not the case that the splitting of consciousness occurs because the patients are weak-minded; they appear to be weak-minded because their mental activity is divided and only a part of its capacity is at the disposal of their conscious thought. We cannot regard mental weakness as the *typus hystericus*, as the essence of the disposition to hysteria.

An example makes plain what is intended by the first of these two sentences. We were frequently able to observe the following course of events with one of our patients (Frau Cäcilie M.). While she was feeling comparatively well a hysterical symptom would appear - a tormenting, obsessive hallucination, a neuralgia, or something of the kind - and would for some time increase in intensity. Simultaneously the patient's mental capacity would continuously decrease, and after a few days any uninitiated observer would have been bound to call her weak-minded. She would then be relieved of the unconscious idea (the memory of a psychical trauma, often belonging to the remote past), either by the physician under hypnosis or by her suddenly describing the event in a state of agitation and to the accompaniment of a lively emotion. When this had happened she did not merely become quiet and cheerful and free from the tormenting symptom; it was always astonishing to observe the width and clarity of her intellect and the acuteness of her understanding and judgement. Chess, which she played excellently, was a favourite occupation of hers, and she enjoyed playing two games at a time, which can scarcely be regarded as indicating a lack of mental synthesis. It was impossible to escape the impression that during a course of events such as we have just described the unconscious idea drew to itself an ever-increasing portion of her psychical activity and that the more this happened the smaller became the part played by conscious thought, till it was reduced to total imbecility; but that when, to use the remarkably apt Viennese expression, she was '*beisammen*' [literally 'together', meaning 'in one's right mind'], she possessed quite remarkable mental powers.

As a comparable state in normal people we would adduce, not concentration of attention, but *preoccupation*. (If someone is 'preoccupied' by some vivid idea, such as a worry, his mental capacity is similarly reduced.

Every observer is largely under the influence of the subjects of his observation, and we are inclined to believe that Janet's views were mainly formed in the course of a detailed study of the feeble-minded hysterical patients who are to be found in hospitals or institutions because they have not been able to hold their own in life on account of their illness and the mental weakness caused by it. Our own observations, carried out on educated hysterical patients, have forced us to take an essentially different view of their minds. In our opinion 'among hysterics may be found people of the clearest intellect, strongest will, greatest character and highest critical power'. No amount of genuine, solid mental endowment is excluded by hysteria, though actual achievements are often made impossible by the illness. After all, the patron saint of hysteria, St. Theresa, was a woman of genius with great practical capacity.

But on the other hand no degree of silliness, incompetence and weakness of will is a protection against hysteria. Even if we disregard what is merely a *result* of the illness, we must recognize the type of feeble-minded hysteric as a common one. Yet even so, what we find here is not torpid, phlegmatic stupidity but an excessive degree of mental mobility which leads to inefficiency. I shall discuss later the question of innate disposition. Here I merely propose to show that Janet's opinion that mental weakness is in any way at the root of hysteria and splitting of the mind is untenable.

In complete opposition to Janet's views, I believe that in a great many cases what underlies dissociation is an excess of efficiency, the habitual co-existence of two heterogeneous trains of ideas. It has frequently been pointed out that we are often not merely 'mechanically' active while our conscious thought is occupied by trains of ideas which have nothing in common with our activity, but that we are also capable of what is undoubtedly psychical functioning while our thoughts are 'busy elsewhere' - as, for instance, when we read aloud correctly and with the appropriate intonation, but afterwards have not the slightest idea of what we have been reading.

There are no doubt a whole number of activities, from mechanical ones such as knitting or playing scales, to some requiring at least a small degree of mental functioning, all of which are performed by many people with only half their mind on them. This is specially true of people who are of a very lively disposition, to whom monotonous, simple and uninteresting occupation is a torture, and who actually begin by deliberately amusing themselves with thinking of something different (cf. Anna O.'s 'private theatre'). Another situation, but a similar one, occurs when an interesting set of ideas, derived for instance from books or plays, forces itself upon the subject's attention and intrudes into his thoughts. This intrusion is still more vigorous if the extraneous set of ideas is strongly coloured with affect (e.g. worry or the longing of someone in love). We then have the state of preoccupation that I have touched upon above, which, however, does not prevent many people from performing fairly complicated actions. Social circumstances often necessitate a duplication of this kind even when the thoughts involved are of an exacting kind, as for instance when a woman who is in the throes of extreme worry or of passionate excitement carries out her social duties and the functions of an affable hostess. We all of us manage minor achievements of this kind in the course of our work; and self-observation seems always to show that the affective group of ideas are not merely aroused from time to time by association but are present in the mind all the time and enter consciousness unless it is taken up with some external impression or act of will.

Even in people who do not habitually allow day-dreams to pass through their minds alongside their usual activity, some situations give rise during considerable periods of time to this simultaneous existence of changing impressions and reactions from external life on the one hand, and an affectively-coloured group of ideas on the other. *Post equitem sedet atra cura* ['black care sits behind the rider']. Among these situations the most prominent are those of looking after someone dear to us who is ill, and of being in love. Experience shows that sick nursing and sexual affects also play the principal part in the majority of the more closely analysed case histories of hysterical patients.

I suspect that the duplication of psychical functioning, whether this is habitual or caused by emotional situations in life, acts as a substantial *predisposition* to a genuine pathological splitting of the mind. This duplication passes over into the latter state if the content of the two co-existing sets of ideas is no longer of the same kind, if one of them contains ideas which are inadmissible to consciousness - which have been fended off, that is, or have arisen from hypnoid states. When this is so, it is impossible for the two temporarily divided streams to reunite, as is constantly happening in healthy people, and a region of unconscious psychical activity becomes permanently split off. This hysterical splitting of the mind stands in the same relation to the 'double ego' of a healthy person as does the hypnoid state to a normal reverie. In this latter contrast what determines the pathological quality is amnesia, and in the former what determines it is the inadmissibility of the ideas to consciousness.

Our first case history, that of Anna O., to which I am obliged to keep on returning, affords a clear insight into what happens. The girl was in the habit, while she was in perfect health, of allowing trains of imaginative ideas to pass through her mind during her ordinary occupations. While she was in a situation that favoured auto-hypnosis, the affect of anxiety entered into her reverie and created a hypnoid state for which she had amnesia. This was repeated on different occasions and its ideational content gradually became richer and richer; but it continued to alternate with states of completely normal waking thought. After four months the hypnoid state gained entire control of the patient. The separate attacks ran into one another and thus an *état de mal* arose, an acute hysteria of the most severe type. This lasted for several months in various forms (the period of somnambulism); it was then forcibly interrupted, and thereafter alternated once again with normal psychical behaviour. But even during her normal behaviour there was a persistence of somatic and psychical phenomena (contractures, hemi-anaesthesia and changes in speech) of which in this case we know as a fact that they were based on ideas belonging to the hypnoid state. This proves that even during her normal behaviour the ideational complex belonging to the hypnoid state, the 'subconsciousness', was in existence and that the split in her mind persisted.

I have no second example to offer of a similar course of development. I think, however, that the case throws some light also on the growth of *traumatic* neuroses. During the first few days after the traumatic event, the state of hypnoid fright is repeated every time the event is recalled. While this state recurs more and more often, its intensity so far diminishes that it no longer *alternates* with waking thought but only exists side by side with it. It now becomes continuous, and the somatic symptoms, which earlier were only present during the attack of fright, acquire a permanent existence. I can, however, only *suspect* that this is what happens, as I have never analysed a case of this kind.

Freud's observations and analyses show that the splitting of the mind can also be caused by 'defence', by the deliberate deflection of consciousness from distressing ideas: only, however, in some people, to whom we must therefore ascribe a mental idiosyncrasy. In normal people, such ideas are either successfully suppressed, in which case they vanish completely, or they are not, in which case they keep on emerging in consciousness. I cannot tell what the nature of this idiosyncrasy is. I only venture to suggest that the assistance of the hypnoid state is necessary if defence is to result not merely in single converted ideas being made into unconscious ones, but in a genuine splitting of the mind. Auto-hypnosis has, so to speak, created the space or region of unconscious psychical activity into which the ideas which are fended off are driven. But, however this may be, the fact of the pathogenic significance of 'defence' is one that we must recognize.

I do not think, however, that the genesis of splitting of the mind is anything like covered by the half-understood processes that we have discussed. Thus, in their initial stages hysterias of a severe degree usually exhibit for a time a syndrome that may be described as acute hysteria. (In the anamnesis of male cases of hysteria we generally come across this form of illness represented as being 'encephalitis'; in female cases ovarian neuralgia leads to a diagnosis of 'peritonitis'.) In this acute stage of hysteria psychotic traits are very distinct, such as manic and angry states of excitement, rapidly changing hysterical phenomena, hallucinations, and so on. In states of this kind the splitting of the mind may perhaps take place in a different manner from that which we have tried to describe above. Perhaps the whole of this stage is to be regarded as a long hypnoid state, the residues of which provide the nucleus of the unconscious ideational complex, while waking thought is amnesic for it. Since we are for the most part ignorant of the causes that lead to an acute hysteria of this kind (for I do not venture to regard the course of events with Anna O. as having general application), there would seem to be another sort of psychical splitting which, in contrast to those discussed above, might be termed irrational.¹ And no doubt yet other forms of this process exist, which are still concealed from our young psychological science; for it is certain that we have only taken the first steps in this region of knowledge, and our present views will be substantially altered by further observations.

¹ I must, however, point out that precisely in the best-known and clearest example of major hysteria with manifest '*double conscience*' - precisely in the case of Anna O. - no residue of the acute stage was carried over into the chronic one, and all the phenomena of the latter had already been produced during the 'incubation period' in hypnoid and affective states.

Let us now enquire what the knowledge of splitting of the mind that has been gained during the last few years has achieved towards an understanding of hysteria. It seems to have been great in amount and in importance.

These discoveries have in the first place made it possible for what are apparently purely somatic symptoms to be traced back to ideas, which, however, are not discoverable in the patients' consciousness. (It is unnecessary to enter into this again.) In the second place, they have taught us to understand hysterical attacks, in part at least, as being products of an unconscious ideational complex. (Cf. Charcot.) But, besides this, they have also explained some of the psychical characteristics of hysteria, and this point perhaps deserves a more detailed discussion.

It is true that 'unconscious ideas' never, or only rarely and with difficulty, enter waking thought; but they influence it. They do so, first, through their consequences - when, for instance, a patient is tormented by a hallucination which is totally unintelligible and senseless, but whose meaning and motivation become clear under hypnosis. Further, they influence association by making certain ideas more vivid than they would have been if they had not been thus reinforced from the unconscious. So particular groups of ideas constantly force themselves on the patient with a certain amount of compulsion and he is obliged to think of them. (The case is similar with Janet's hemi-anaesthetic patients. When their anaesthetic hand is repeatedly touched they feel nothing; but when they are told to name any number they like, they always choose the one corresponding to the number of times they have been touched.) Again, unconscious ideas govern the patient's emotional tone, his state of feeling. When, in the course of unrolling her memories, Anna O. approached an event which had originally been bound up with a lively affect, the corresponding feeling made its appearance several days in advance and before the recollection appeared clearly even in her hypnotic consciousness.

This makes the patients' 'moods' intelligible - their inexplicable, unreasonable changes of feeling which seem to waking thought without motive. The impressionability of hysterical patients is indeed to a large extent determined simply by their innate excitability; but the lively affects into which they are thrown by relatively trivial causes become more intelligible if we reflect that the 'split-off mind' acts like a sounding-board to the note of a tuning-fork. Any event that provokes unconscious memories liberates the whole affective force of these ideas that have not undergone a wearing-away, and the affect that is called up is then quite out of proportion to any that would have arisen in the conscious mind alone.

I have spoken above (p. 208 f.) of a patient whose psychical functioning always stood in inverse ratio to the vividness of her unconscious ideas. The diminution of her conscious thinking was based partly, but only partly, on a peculiar kind of abstraction. After each of her momentary '*absences*' - and these were constantly occurring - she did not know what she had thought of in the course of it. She oscillated between her '*conditions primes*' and '*secondes*', between the conscious and the unconscious ideational complexes. But it was not only on that account that her psychical functioning was reduced, nor on account of the affect which dominated her from the unconscious. While she was in this state her waking thought was without energy, her judgement was childish and she seemed, as I have said, positively imbecile. I believe that this was due to the fact that waking thought has less energy at its disposal if a great amount of psychical excitation is appropriated by the unconscious.

If this state of things is not merely temporary, if the split-off mind is in a *constant* state of excitation, as it was with Janet's hemi-anaesthetic patients - in whom, moreover, all the sensations in no less than one half of the body were perceived only by the unconscious mind - if this is the case, so little cerebral functioning is left over for waking thought that the weakness of mind which Janet describes and regards as innate is fully accounted for. There are only very few people of whom it could be said, as of Uhland's Bertrand de Born, that they never need more than half their mind. Such a reduction in their psychical energy does make the majority of people weak-minded.

This weakness of mind caused by a splitting of the psyche seems also to be a basis of a momentous characteristic of some hysterical patients - their suggestibility. (I say 'some', since it is certain that among hysterical patients are to be found people of the soundest and most critical judgement as well.)

By suggestibility we understand, in the first instance, only an inability to criticize ideas and complexes of ideas (judgements) which emerge in the subject's own consciousness or are introduced into it from outside through the spoken word or through reading. All criticism of ideas like these which come freshly into consciousness is based on the fact that they awaken other ideas by association and amongst them some that are irreconcilable with the fresh ones. The resistance to these latter is thus dependent on the store of antagonistic ideas in potential consciousness, and the strength of the resistance corresponds to the ratio between the vividness of the fresh ideas and that of those aroused from memory. Even in normal intellects this ratio is very various. What we describe as an intellectual temperament depends on it to a great extent. A 'sanguine' man is always delighted by new people and things, and this is no doubt so because the intensity of his mnemonic images is less in comparison with that of new impressions than it is in a quieter, 'phlegmatic' man. In pathological states the preponderance of fresh ideas and the lack of resistance to them increases in proportion to the fewness of the mnemonic images aroused - that is, in proportion to the weakness and poorness of their associative powers. This is already what happens in sleep and dreams, in hypnosis and whenever there is a reduction in mental energy, so long as this does not also reduce the vividness of the fresh ideas.

The unconscious, split-off mind in hysteria is pre-eminently suggestible on account of the poverty and incompleteness of its ideational content. But the suggestibility of the conscious mind, too, in some hysterical patients seems to be based on this. They are excitable from their innate disposition; in them, fresh ideas are very vivid. In contrast to this, their intellectual activity proper, their associative function, is reduced, because only a part of their psychical energy is at the disposal of their waking thought, owing to a splitting-off of an 'unconscious'. As a result of this their power of resistance both to auto- and allo-suggestions is diminished and sometimes abolished. The suggestibility of their *will* also seems to be due to this alone. On the other hand, *hallucinatory* suggestibility, which promptly changes every idea of a sense-perception into an actual perception, demands, like all hallucinations, an abnormal degree of excitability of the perceptual organ and cannot be traced back solely to a splitting of the mind.

(6) INNATE DISPOSITION - DEVELOPMENT OF HYSTERIA

At almost every stage of these discussions I have been obliged to recognize that most of the phenomena which we have been endeavouring to understand can be based, among other things, on an innate idiosyncrasy. This defies any explanation that seeks to go beyond a mere statement of the facts. But the *capacity to acquire* hysteria is also undoubtedly linked with an idiosyncrasy of the person concerned, and an attempt to define it more accurately will perhaps not be entirely unprofitable.

I have explained above why I cannot accept Janet's view that the disposition to hysteria is based on innate psychical weakness. The medical practitioner who, in his capacity as family doctor, observes the members of hysterical families of all ages will certainly be inclined to regard this disposition as lying in an excess rather than in a defect. Adolescents who are later to become hysterical are for the most part lively, gifted and full of intellectual interests before they fall ill. Their energy of will is often remarkable. They include girls who get out of bed at night so as secretly to carry on some study that their parents have forbidden from fear of their overworking. The capacity for forming sound judgements is certainly not more abundant in them than in other people; but it is rare to find in them simple, dull intellectual inertia and stupidity. The overflowing productivity of their minds has led one of my friends to assert that hysterics are the flower of mankind, as sterile, no doubt, but as beautiful as double flowers.

Their liveliness and restlessness, their craving for sensations and mental activity, their intolerance of monotony and boredom, may be formulated thus: they are among those people whose nervous system while it is at rest liberates excess of excitation which requires to be made use of (cf. p. 175). During development at puberty, and in consequence of it, this original excess is supplemented by the powerful increase in excitation which arises from the awakening of sexuality, from the sex glands. From then on there is a surplus quantity of free nervous energy available for the production of pathological phenomena.

But in order for these phenomena to appear in the form of hysterical symptoms there must evidently also be another, specific idiosyncrasy in the individual concerned. For after all, the great majority of lively and excitable people do not become hysterical. I was only able, above, to describe this idiosyncrasy in the vague and unenlightening phrase, 'abnormal excitability of the nervous system'. But it may be possible to go further and say that this abnormality lies in the fact that in such people the excitation of the central organ can flow into the sensory nervous apparatuses which are normally accessible only to peripheral stimuli, as well as into the nervous apparatuses of the vegetative organs which are isolated from the central nervous system by powerful resistances. It may be that this idea of there being a surplus of excitation constantly present which has access to the sensory, vasomotor and visceral apparatuses already accounts for some pathological phenomena.

In people of this kind, as soon as their attention is forcibly concentrated on some part of the body, what Exner speaks of as the 'facilitation of attention' in the sensory path of conduction concerned exceeds the normal amount. The free, floating excitation is, as it were, diverted into this path, and a local hyperalgesia is produced. As a result, every pain, however caused, reaches maximum intensity, every ailment is 'fearful' and 'unbearable'. Further, whereas in normal people a quantity of excitation, after cathecting a sensory path, always leaves it again, this is not so in these cases. That quantity, moreover, not only remains behind but is constantly increased by the influx of fresh excitations. A slight injury to a joint thus leads to arthralgia, and the painful sensations due to ovarian swelling lead to chronic ovarian neuralgia; and since the nervous apparatuses of the circulation are more accessible to cerebral influence than in normal people, we find nervous palpitation of the heart, a tendency to fainting, proneness to excessive blushing and turning pale, and so on.

However, it is not only in regard to *central* influences that the peripheral nervous apparatuses are more easily excitable. They also react in an excessive and perverse fashion to appropriate, functional stimuli. Palpitations follow from moderate effort no less than from emotional excitement, and the vasomotor nerves cause the arteries to contract ('dead fingers'), apart from any psychical influence. And just as a slight injury leaves behind an arthralgia, a short attack of bronchitis is followed by nervous asthma, and indigestion by frequent cardiac pains. We must accordingly recognize that accessibility to sums of excitation of central origin is no more than a special case of general abnormal excitability,¹ even though it is the most important one from the point of view of our present topic.

¹ Oppenheim's 'instability of the molecules'.

It seems to me, therefore, that the old 'reflex theory' of these symptoms, which would perhaps be better described simply as 'nervous' ones but which form part of the empirical clinical picture of hysteria, should not be completely rejected. The vomiting, which of course accompanies the dilatation of the uterus in pregnancy, may, where there is abnormal excitability quite well be set going in a reflex manner by trivial uterine stimuli, or perhaps even by the periodic changes in size of the ovaries. We are acquainted with so many remote effects resulting from organic changes, so many strange instances of 'referred pain', that we cannot reject the possibility that a host of nervous symptoms which are sometimes determined psychically may in other cases be remote effects of reflex action. Indeed, I venture to put forward the highly unmodern heresy that even motor weakness in a leg may sometimes be determined by a genital affection, not psychically, but by direct reflex action. I think we shall do well not to insist too much on the exclusiveness of our new discoveries or to seek to apply them in all cases.

Other forms of abnormal sensory excitability still escape our understanding completely: general analgesia, for instance anaesthetic areas, real restriction of the field of vision, and so on. It is possible and perhaps probable that further observations will prove the psychical origin of one or other of these stigmata and so explain the symptom; but this has not yet happened (for I do not venture to generalize the findings presented by our first case history), and I do not think it is justifiable to presume that this is their origin before it has been properly traced.

On the other hand the idiosyncrasy of the nervous system and of the mind which we have been discussing seems to explain one or two very familiar properties of many hysterical patients. The surplus of excitation which is liberated by their nervous system when in a state of rest determines their incapacity to tolerate a monotonous life and boredom - their craving for sensations which drives them, after the onset of their illness, to interrupt the monotony of their invalid life by all kinds of 'incidents', of which the most prominent are from the nature of things pathological phenomena. They are often supported in this by autosuggestion. They are led further and further along this road by their need for being ill, a remarkable trait which is as pathognomonic for hysteria as is *fear* of being ill for hypochondria. I know a hysterical woman who inflicted on herself injuries which were often quite severe, merely for her own use and without those about her or her physician learning of them. If she did nothing else she used to play all kinds of tricks while she was alone in her room simply to prove to herself that she was not normal. For she had in fact a distinct feeling of not being well and could not discharge her duties satisfactorily, and she tried to justify herself in her own eyes by actions such as these. Another patient, a very sick woman suffering from pathological conscientiousness and full of distrust of herself, felt every hysterical phenomenon as something guilty, because, she said, she need not have had it if she had really wanted not to. When a paresis of her legs was wrongly diagnosed as a disease of the spine she felt it as an immense relief, and when she was told that it was 'only nervous' and would pass off, that was enough to bring on severe pangs of conscience. The need to be ill arises from the patient's desire to convince herself and other people of the reality of her illness. When this need is further associated to the distress caused by the monotony of a sick-room, the inclination to produce more and more new symptoms is developed to its fullest.

If, however, this turns into deceitfulness and actual simulation (and I think that we now err just as far on the side of denying simulation as we used to on the side of accepting it), that is based, not on the hysterical disposition but, as Moebius has so aptly said, on its being complicated by other forms of degeneracy - by innate, moral inferiority. In just the same way the 'malicious hysteric' comes into existence when someone who is innately excitable but poor in emotion is also a victim to the egoistic stunting of character which is so easily produced by chronic ill-health. Incidentally, the 'malicious hysteric' is scarcely commoner than the malicious patient in the later stages of tabes.

A surplus of excitation also gives rise to pathological phenomena in the motor sphere. Children having this characteristic very easily develop *tic*-like movements. These may be started in the first instance by some sensation in the eyes or face or by an uncomfortable article of clothing, but they become permanent unless they are promptly checked. The reflex paths are very easily and quickly dug in deep.

Nor can the possibility be dismissed of there being purely motor convulsive attacks which are independent of any psychical factor and in which all that happens is that the mass of excitation accumulated by summation is discharged, in just the same way as the mass of stimuli caused by anatomical modifications is discharged in an epileptic fit. Here we should have the non-ideogenic hysterical convulsion.

We so often find adolescents who had previously been healthy, though excitable, falling ill of hysteria during pubertal development, that we must ask ourselves whether that process may not create the disposition to hysteria where it was not present innately. And in any case we must attribute more to it than a simple raising of the quantity of excitation. Sexual maturation impinges on the whole nervous system, increasing excitability and reducing resistances everywhere. We are taught this from the observation of adolescents who are not hysterical and we are thus justified in believing that sexual maturation also establishes the hysterical disposition in so far as it consists precisely in this characteristic of the nervous system. In saying this we are already recognizing sexuality as one of the major components of hysteria. We shall see that the part it plays in it is very much greater still and that it contributes in the most various ways to the constitution of the illness.

If the stigmata spring directly from this innate breeding ground of hysteria and are not of ideogenic origin, it is also impossible to give ideogenesis such a central position in hysteria as is sometimes done nowadays. What could be more genuinely hysterical than the stigmata? They are pathognomonic findings which establish the diagnosis; and yet precisely they seem not to be ideogenic. But if the basis of hysteria is an idiosyncrasy of the whole nervous system, the complex of ideogenic, psychically determined symptoms is erected on it as a building is on its foundations. And it is a building of *several storeys*. Just as it is only possible to understand the structure of such a building if we distinguish the plans of the different floors, it is, I think, necessary in order to understand hysteria for us to pay attention to the various kinds of complication in the causation of the symptoms. If we disregard them and try to carry through an explanation of hysteria by employing a single causal nexus, we shall always find a very large residue of unexplained phenomena left over. It is just as though we tried to insert the different rooms of a many-storeyed house into the plan of a single storey.

Like the stigmata, a number of other nervous symptoms - some pains and vasomotor phenomena and perhaps purely motor convulsive attacks - are, as we have seen, not caused by ideas but are direct results of the fundamental abnormality of the nervous system.

Closest to them are the ideogenic phenomena which are simply conversions of affective excitation (p. 181). They arise as the consequences of affects in people with a hysterical disposition and in the first instance they are only an 'abnormal expression of the emotions' (Oppenheim).¹ This becomes by repetition a genuine and apparently purely somatic hysterical symptom, while the idea that gave rise to it becomes unnoticeable (p. 184) or is fended off and therefore repressed from consciousness. The most numerous and important of the ideas that are fended off and converted have a sexual content. They are at the bottom of a great deal of the hysteria of puberty. Girls who are approaching maturity - and it is they who are chiefly concerned - behave very differently towards the sexual ideas and feelings which crowd in on them. Some girls meet them with complete unembarrassment, among whom a few ignore and overlook the whole subject. Others accept them like boys, and this is no doubt the rule with peasant and working class girls. Others again, with more or less perverse curiosity, run after anything sexual that they can get hold of in talk or books. And lastly there are natures of a refined organization who, though their sexual excitability is great, have an equally great moral purity and who feel that anything sexual is something incompatible with their ethical standards, something dirtying and smirching.² They repress sexuality from their consciousness, and the affective ideas with a content of this kind which have caused the somatic phenomena are fended off and thus become unconscious.

¹ This disposition is nothing else than what Strümpell speaks of as the 'disturbance in the psycho-physical sphere' which underlies hysteria.

² Some observations lead us to believe that the fear of touching, or, more properly, the fear of being dirtied, which compels women to keep on washing their hands all the time, very often has this derivation. Their washing is derived from the same mental process as Lady Macbeth's.

The tendency towards fending off what is sexual is further intensified by the fact that in young unmarried women sensual excitation has an admixture of anxiety, of fear of what is coming, what is unknown and half-suspected, whereas in normal and healthy young men it is an unmixed aggressive instinct. The girl senses in Eros the terrible power which governs and decides her destiny and she is frightened by it. All the greater, then, is her inclination to look away and to repress from her consciousness the thing that frightens her.

Marriage brings fresh sexual traumas. It is surprising that the wedding night does not have pathogenic effects more frequently, since unfortunately what it involves is so often not an erotic seduction but a violation. But indeed it is not rare to find in young married women hysterias which can be traced back to this and which vanish if in the course of time sexual enjoyment emerges and wipes out the trauma. Sexual traumas also occur in the later course of many marriages. The case histories from whose publication we have been obliged to refrain include a great number of them - perverse demands made by the husband, unnatural practices, etc. I do not think I am exaggerating when I assert that *the great majority of severe neuroses in women have their origin in the marriage bed*.¹

Certain sexual noxae, which consist essentially in insufficient satisfaction (*coitus interruptus*, *ejaculatio praecox*, etc.), result according to the discovery of Freud (1895*b*) not in hysteria but in an anxiety neurosis. I am of opinion, however, that even in such cases the excitation of the sexual affect is quite frequently converted into hysterical somatic phenomena.

It is self-evident and is also sufficiently proved by our observations that the non-sexual affects of fright, anxiety and anger lead to the development of hysterical phenomena. But it is perhaps worth while insisting again and again that the sexual factor is by far the most important and the most productive of pathological results. The unsophisticated observations of our predecessors, the residue of which is preserved in the term 'hysteria', came nearer the truth than the more recent view which puts sexuality almost last, in order to save the patients from moral reproaches. The sexual needs of hysterical patients are no doubt just as variable in degree from individual to individual as in healthy people and are no stronger than in them; but the former fall ill from them, and, for the most part, precisely owing to struggling against them, owing to their *defence* against sexuality.

Alongside sexual hysteria we must at this point recall hysteria due to fright - traumatic hysteria proper - which constitutes one of the best known and recognized forms of hysteria.

In what may be called the same stratum as the phenomena which arise from the conversion of affective excitation are to be found those which owe their origin to suggestion (mostly auto-suggestion) in individuals who are innately suggestible. A high degree of suggestibility - that is to say, the unrestricted preponderance of ideas that have been freshly aroused - is not among the essential features of hysteria. It can, however, be present as a complication in people with a hysterical disposition, in whom this very idiosyncrasy of the nervous system makes possible the somatic realization of supervalent ['Überwertig'] ideas. Moreover, it is for the most part only *affective* ideas which are realized in somatic phenomena by suggestion, and consequently the process may often be regarded as a conversion of the accompanying affect of fright or anxiety.

These processes - the conversion of affect, and suggestion - remain identical even in the complicated forms of hysteria which we must now consider. They merely find more favourable conditions in such cases: it is invariably through one of these two processes that psychically-determined hysterical phenomena come into being.

¹ It is a most unfortunate thing that clinical medicine ignores one of the most important of all the pathogenic factors or at least only hints at it delicately. This is certainly a subject in which the acquired knowledge of experienced physicians should be communicated to their juniors, who as a rule blindly overlook sexuality - at all events so far as their patients are concerned.

The third constituent of the hysterical disposition, which appears in some cases in addition to those that have been already discussed, is the hypnoid state, the tendency to auto-hypnosis (p. 192). This state favours and facilitates in the greatest degree both conversion and suggestion; and in this way it erects, as we might say, on the top of the minor hysterias, the higher storey of major hysteria. The tendency to auto-hypnosis is a state which is to begin with only temporary and which alternates with the normal one. We may attribute to it the same increase of mental influence on the body that we observe in artificial hypnosis. This influence is all the more intense and deep-going here in that it is acting upon a nervous system which even outside hypnosis is abnormally excitable.¹ We cannot tell how far and in what cases the tendency to auto-hypnosis is an innate property of the organism. I have expressed the view above (pp. 195-196) that it develops from reveries that are charged with affect. But there can be no doubt that innate disposition plays a part in this as well. If this view is correct, it will be clear here once again how great an influence on the development of hysteria is to be ascribed to sexuality. For, apart from sick-nursing, no psychical factor is so well-calculated to produce reveries charged with affect as are the longings of a person in love. And over and above this the sexual orgasm itself, with its wealth of affect and its restriction of consciousness, is closely akin to hypnoid states.

The hypnoid element is most clearly manifested in hysterical attacks and in those states which can be described as acute hysteria and which, it seems, play such an important part in the development of hysteria (p. 213). These are obviously psychotic states which persist for a long time, often for several months and which it is frequently necessary to describe as hallucinatory confusion. Even if the disturbance does not go as far as this, a great variety of hysterical phenomena emerge in it, a few of which actually persist after it is over. The psychical content of these states consists partly in precisely the ideas which have been fended off in waking life and repressed from consciousness. (Cf. the 'hysterical deliria in saints and nuns, continent women and well-brought-up children'.)

¹ It is tempting to identify the disposition to hypnosis with innate abnormal excitability; for artificial hypnosis, too, exhibits ideogenic changes in secretion and local blood-supply, formation of vesicles, etc. This seems to be the view held by Moebius. But in my opinion it would involve us in a vicious circle. The miraculous workings of hypnosis are, so far as I can see, only observable in hysterical patients. What we should be doing would be first to assign the phenomena of hysteria to hypnosis, and then to assert that hypnosis is the cause of those phenomena.

Since these states are so often nothing less than psychoses and are yet derived immediately and exclusively from hysteria, I cannot agree with Moebius's opinion that 'apart from the deliria attached to attacks, it is impossible to speak of an actual hysterical insanity' (1895, 18). In many cases these states constitute an insanity of this kind; and psychoses like these also recur in the further course of a hysteria. It is true that essentially they are nothing other than the psychotic stage of an attack, but since they last for months they can nevertheless hardly be described as attacks.

How does one of these acute hysterias arise? In the best known case (Case History 1) it developed out of an accumulation of hypnoid attacks; in another case (where there was already a complicated hysteria present) it arose in association with a withdrawal of morphine. The process is for the most part completely obscure and awaits clarification from further observations.

Accordingly, we may apply to the hysterias which have been discussed here Moebius's pronouncement (*ibid.*, 16): 'The essential change that occurs in hysteria is that the mental state of the hysterical patient becomes temporarily or permanently similar to that of a hypnotized subject.'

The persistence in the normal state of the symptoms that have arisen during the hypnoid one corresponds entirely to our experiences with post-hypnotic suggestion. But this already implies that complexes of ideas that are inadmissible to consciousness co-exist with the trains of ideas that pursue a conscious course, that the splitting of the mind has taken place (p. 206). It seems certain that this can happen even without a hypnoid state, from the wealth of thoughts which have been fended off and repressed from consciousness but not suppressed. In one way or another there comes into existence a region of mental life - sometimes poor in ideas and rudimentary, sometimes more or less on a par with waking thought - our knowledge of which we owe, above all, to Binet and Janet. The splitting of the mind is the consummation of hysteria. I have shown above (in Section 5) how it explains the principal characteristics of the disorder. One part of the patient's mind is in the hypnoid state, permanently, but with a varying degree of vividness in its ideas, and is always prepared whenever there is a lapse in waking thought to assume control over the whole person (e. g. in an attack or delirium). This occurs as soon as a powerful affect interrupts the normal course of ideas, in twilight states and states of exhaustion. Out of this persisting hypnoid state unmotivated ideas, alien to normal association, force their way into consciousness, hallucinations are introduced into the perceptual system and motor acts are innervated independently of the conscious will. This hypnoid mind is in the highest degree susceptible to conversion of affects and to suggestion, and thus fresh hysterical phenomena appear easily, which without the split in the mind would only have come about with great difficulty and under the pressure of repeated affects. The split-off mind is the devil with which the unsophisticated observation of early superstitious times believed that these patients were possessed. It is true that a spirit alien to the patient's waking consciousness holds sway in him; but the spirit is not in fact an alien one, but a part of his own.

The attempt that has been made here to make a synthetic construction of hysteria out of what we know of it to-day is open to the reproach of eclecticism, if such a reproach can be justified at all. There were so many formulations of hysteria, from the old 'reflex theory' to the 'dissociation of personality', which have had to find a place in it. But it can scarcely be otherwise; for so many excellent observers and acute minds have concerned themselves with hysteria. It is unlikely that any of their formulations was without a portion of the truth. A future exposition of the true state of affairs will certainly, include them all and will merely combine all the one-sided views of the subject into a corporate reality. Eclecticism, therefore, seems to me nothing to be ashamed of.

But how far we still are to-day from the possibility of any such complete understanding of hysteria! With what uncertain strokes have its outlines been drawn in these pages, with what clumsy hypotheses have the gaping lacunas been concealed rather than bridged! Only one consideration is to some extent consoling: that this defect attaches, and must attach, to all physiological expositions of complicated psychical processes. We must always say of them what Theseus in *A Midsummer Night's Dream* says of tragedy: 'The best in this kind are but shadows.' And even the weakest is not without value if it honestly and modestly tries to hold on to the outlines of the shadows which the unknown real objects throw upon the wall. For then, in spite of everything, the hope is always justified that there may be some degree of correspondence and similarity between the real processes and our idea of them.

Studies On Hysteria

THE PSYCHOTHERAPY OF HYSTERIA

(FREUD)

IV

THE PSYCHOTHERAPY OF HYSTERIA

(FREUD)

In our 'Preliminary Communication' we reported how, in the course of our investigation into the aetiology of hysterical symptoms, we also came upon a therapeutic method which seemed to us of practical importance. For 'we found, to our great surprise at first, that *each individual hysterical symptom immediately and permanently disappeared when we had succeeded in bringing clearly to light the memory of the event by which it was provoked and in arousing its accompanying affect, and when the patient had described that event in the greatest possible detail and had put the affect into words*'. (p. 9.)

We further endeavoured to explain the way in which our psychotherapeutic method works. '*It brings to an end the operative force of the idea which was not abreacted in the first instance, by allowing its strangulated affect to find a way through to speech; and it subjects it to associative correction by introducing it into normal consciousness (under light hypnosis) or by removing it through the physician's suggestion, as is done in somnambulism accompanied by amnesia*.' (p. 19.)

I will now try to give a connected account of how far this method carries us, of the respects in which it achieves more than other methods, of the technique by which it works and of the difficulties it meets with. Much of the substance of this is already contained in the case histories printed in the earlier portion of this book, and I shall not be able to avoid repeating myself in the account which follows.

(1)

For my own part, I too may say that I can still hold by what is contained in the 'Preliminary Communication'. None the less I must confess that during the years which have since passed - in which I have been unceasingly concerned with the problems touched upon in it - fresh points of view have forced themselves on my mind. These have led to what is in part at least a different grouping and interpretation of the factual material known to me at that time. It would be unfair if I were to try to lay too much of the responsibility for this development upon my honoured friend Dr. Josef Breuer. For this reason the considerations which follow stand principally under my own name.

When I attempted to apply to a comparatively large number of patients Breuer's method of treating hysterical symptoms by an investigation and abreaction of them under hypnosis, I came up against two difficulties, in the course of dealing with which I was led to an alteration both in my technique and in my view of the facts. (1) I found that not everyone could be hypnotized who exhibited undoubted hysterical symptoms and who, it was highly probable, was governed by the same psychical mechanism. (2) I was forced to take up a position on the question of what, after all, essentially characterizes hysteria and what distinguishes it from other neuroses.

I will put off until later my account of how I got over the first of these two difficulties and what I have learnt from it, and I will begin by describing the attitude I adopted in my daily practice towards the second problem. It is very hard to obtain a clear view of a case of neurosis before one has submitted it to a thorough analysis - an analysis which can, in fact, only be brought about by the use of Breuer's method; but a decision on the diagnosis and the form of therapy to be adopted has to be made before any such thorough knowledge of the case has been arrived at. The only course open to me, therefore, was to select for cathartic treatment such cases as could be provisionally diagnosed as hysteria, which exhibited one or more of the stigmata or characteristic symptoms of hysteria. It then sometimes happened that in spite of the diagnosis of hysteria the therapeutic results turned out to be very scanty and that even analysis brought nothing significant to light. On other occasions again, I tried applying Breuer's method of treatment to neuroses which no one could have mistaken for hysteria, and I found that in that manner they could be influenced and indeed cleared up. I had this experience, for instance, with obsessional ideas, genuine obsessional ideas of the Westphal type, in cases without a single trait which recalled hysteria. Consequently, the psychical mechanism revealed by the 'Preliminary Communication' could not be pathognomonic for hysteria. Nor could I resolve, merely for the sake of preserving that mechanism as a criterion of it, to lump all these other neuroses in with hysteria. I eventually found a way out of all these emerging doubts by the plan of treating all the other neuroses in question in the same way as hysteria. I determined to investigate their aetiology and the nature of their psychical mechanism in every case and to let the decision as to whether the diagnosis of hysteria was justified depend upon the outcome of that investigation.

Thus, starting out from Breuer's method, I found myself engaged in a consideration of the aetiology and mechanism of the neuroses in general. I was fortunate enough to arrive at some serviceable findings in a relatively short time. In the first place I was obliged to recognize that, in so far as one can speak of determining causes which lead to the *acquisition* of neuroses, their aetiology is to be looked for in *sexual* factors. There followed the discovery that different sexual factors, in the most general sense, produce different pictures of neurotic disorders. And it then became possible, in the degree to which this relation was confirmed, to venture on using aetiology for the purpose of characterizing the neuroses and of making a sharp distinction between the clinical pictures of the various neuroses. Where the aetiological characteristics coincided regularly with the clinical ones, this was of course justified.

In this manner I found that neurasthenia presented a monotonous clinical picture in which, as my analyses showed, a 'psychical mechanism' played no part. There was a sharp distinction between neurasthenia and 'obsessional neurosis', the neurosis of obsessional ideas proper. In this latter one I was able to recognize a complicated psychical mechanism, an aetiology similar to that of hysteria and an extensive possibility of reducing it by psychotherapy. On the other hand, it seemed to me absolutely necessary to detach from neurasthenia a complex of neurotic symptoms which depend on a quite different and indeed at bottom a *contrary* aetiology. The component symptoms of this complex are united by a characteristic which has already been recognized by Hecker (1893). For they are either symptoms or equivalents and rudiments of *manifestations of anxiety*; and for this reason I have given to this complex which is to be detached from neurasthenia the name of 'anxiety neurosis'. I have maintained that it arises from, an accumulation of physical tension, which is itself once more of sexual origin. This neurosis, too, has no psychical mechanism, but it invariably influences mental life, so that 'anxious expectation', phobias, hyperaesthesia to pains, etc., are among its regular manifestations. This anxiety neurosis, in my sense of the term, no doubt coincides in part with the neurosis which, under the name of 'hypochondria', finds a place in not a few descriptions alongside hysteria and neurasthenia. But I cannot regard the delimitation of hypochondria in any of the works in question as being the correct one, and the applicability of its name seems to me to be prejudiced by the fixed connection of that term with the symptom of 'fear of illness'.

After I had in this way fixed the simple pictures of neurasthenia, anxiety neurosis and obsessional ideas, I went on to consider the cases of neurosis which are commonly included under the diagnosis of hysteria. I reflected that it was not right to stamp a neurosis as a whole as hysterical because a few hysterical signs were prominent in its complex of symptoms. I could well understand this practice, since after all hysteria is the oldest, best-known and most striking of the neuroses under consideration; but it was an abuse, for it put down to the account of hysteria so many traits of perversion and degeneracy. Whenever a hysterical sign, such as an anaesthesia or a characteristic attack, was found in a complicated case of psychical degeneracy, the whole condition was described as one of 'hysteria', so that it is not surprising that the worst and the most contradictory things were found together under this label. But just as it was certain that *this* diagnosis was incorrect, it was equally certain that we ought also to separate out the various neuroses; and since we were acquainted with neurasthenia, anxiety neurosis, etc., in a pure form, there was no longer any need to overlook them in the combined picture.

The following view, therefore, seemed to be the more probable one. The neuroses which commonly occur are mostly to be described as 'mixed'. Neurasthenia and anxiety neuroses are easily found in pure forms as well, especially in young people. Pure forms of hysteria and obsessional neurosis are rare; as a rule these two neuroses are combined with anxiety neurosis. The reason why mixed neuroses occur so frequently is that their aetiological factors are so often intermixed, sometimes only by chance, sometimes as a result of causal relations between the processes from which the aetiological factors of the neuroses are derived. There is no difficulty in tracing this out and demonstrating it in detail. As regards hysteria, however, it follows that that disorder can scarcely be segregated from the nexus of the sexual neuroses for the purposes of study, that as a rule it represents only a single side, only one aspect, of a complicated case of neurosis, and that it is only in marginal cases that it can be found and treated in isolation. We may perhaps say in a number of instances: *a potiori fit denominatio* [i.e. it has been given its name from its more important feature].

I will now examine the case histories that have been reported here, with a view to seeing whether they speak in favour of my opinion that hysteria is not an independent clinical entity.

Breuer's patient, Anna O., seems to contradict my opinion and to be an example of a pure hysterical disorder. This case, however, which has been so fruitful for our knowledge of hysteria, was not considered at all by its observer from the point of view of a sexual neurosis, and is now quite useless for this purpose. When I began to analyse the second patient, Frau Emmy von N., the expectation of a sexual neurosis being the basis of hysteria was fairly remote from my mind. I had come fresh from the school of Charcot, and I regarded the linking of hysteria with the topic of sexuality as a sort of insult - just as the women patients themselves do. When I go through my notes on this case to-day there seems to me no doubt at all that it must be looked on as a case of severe anxiety neurosis accompanied by anxious expectation and phobias - an anxiety neurosis which originated from sexual abstinence and had become combined with hysteria. Case 3, that of Miss Lucy R., can perhaps best be described as a marginal case of pure hysteria. It was a short hysteria which ran an episodic course and had an unmistakable sexual aetiology, such as would correspond to an anxiety neurosis. The patient was an over-mature girl with a need to be loved, whose affections had been too hastily aroused through a misunderstanding. The anxiety neurosis, however, did not become visible, or it escaped me. Case 4, Katharina, was nothing less than a model of what I have described as 'virginal anxiety'. It was a combination of anxiety neurosis and hysteria. The former created the symptoms, while the latter repeated them and operated with them. Incidentally, it was a case typical of a large number of neuroses in young people that are described as 'hysteria'. Case 5, that of Fräulein Elisabeth von R., was once again not investigated as a sexual neurosis. I was only able to express, without confirming it, a suspicion that a spinal neurasthenia may have been its basis.

I must add, though, that in the meantime pure hysterias have become even rarer in my experience. If it was possible for me to bring together these four cases as hysterias and if in reporting them I was able to overlook the points of view that were of importance as regards sexual neuroses, the reason is that these histories date some distance back, and that I did not at that time as yet submit such cases to a deliberate and searching investigation of their neurotic sexual foundation. And if, instead of these four, I did not report *twelve* cases whose analysis provides a confirmation of the psychical mechanism of hysterical phenomena put forward by us, this reticence was necessitated by the very circumstance that the analysis revealed these cases as being simultaneously sexual neuroses, although certainly no diagnostician would have refused them the name of hysteria. But an elucidation of these sexual neuroses would overstep the bounds of the present joint publication.

I should not like it to be wrongly thought that I do not wish to allow that hysteria is an independent neurotic affection, that I regard it merely as a psychical manifestation of anxiety neurosis and that I attribute to it 'ideogenic' symptoms only and am transferring the somatic symptoms (such as hysterogenic points and anaesthesias) to anxiety neurosis. Nothing of the sort. In my opinion it is possible to deal with hysteria, freed from any admixture, as something independent; and to do so in every respect except in that of therapeutics. For in therapeutics we are concerned with a practical aim, with getting rid of the pathological state as a whole. And if hysteria generally appears as a component of a mixed neurosis, the situation resembles that in which there is a mixed infection, where preserving life sets a problem which does not coincide with that of combating the operation of one particular pathogenic agent.

It is very important for me to distinguish the part played by hysteria in the picture of the mixed neuroses from that played by neurasthenia, anxiety neurosis and so on, because, once I have made this distinction, I shall be able to express concisely the therapeutic value of the cathartic method. For I am inclined to venture the assertion that that method is - as a matter of theory - very well able to get rid of any hysterical symptom, whereas, as will be easily understood, it is completely powerless against the phenomena of neurasthenia and is only able rarely and in roundabout ways to influence the psychical effects of anxiety neurosis. Its therapeutic effectiveness in any particular case will accordingly depend on whether the hysterical components of the clinical picture do or do not assume a position of practical importance in comparison with the other neurotic components.

There is another obstacle in the way of the effectiveness of the cathartic method, which we have already indicated in the 'Preliminary Communication'. It cannot affect the underlying causes of hysteria: thus it cannot prevent fresh symptoms from taking the place of the ones which had been got rid of. On the whole, then, I must claim a prominent place for our therapeutic method as employed within the framework of a therapy of the neuroses; but I should like to advise against assessing its value or applying it outside this framework. Since, however, I cannot in these pages offer a 'therapy of the neuroses' of the sort needed by practitioners, what I have just said is equivalent to postponing my account of the subject to a possible later publication. But I am able, I think, to add the following remarks by way of expansion and elucidation.

(1) I do not maintain that I have actually got rid of all the hysterical symptoms that I have undertaken to influence by the cathartic method. But it is my opinion that the obstacles have lain in the personal circumstances of the patients and have not been due to any question of theory. I am justified in leaving these unsuccessful cases out of account in arriving at a judgement, just as a surgeon disregards cases of death which occur under anaesthesia, owing to post-operational haemorrhage, accidental sepsis, etc., in making a decision about a new technique. When I come to deal with the difficulties and drawbacks of the procedure later on, I shall return to a consideration of failures from this source.

(2) The cathartic method is not to be regarded as worthless because it is a symptomatic and not a causal one. For a causal therapy is in fact as a rule only a prophylactic one; it brings to a halt any further effects of the noxious agency, but does not therefore necessarily get rid of the results which that agency has already brought about. As a rule a second phase of treatment is required to perform this latter task, and in cases of hysteria the cathartic method is quite invaluable for this purpose.

(3) Where a period of hysterical production, an acute hysterical paroxysm, has been overcome and all that is left over are hysterical symptoms in the shape of residual phenomena, the cathartic method suffices for every indication and brings about complete and permanent successes. A favourable therapeutic constellation of this kind is not seldom to be found precisely in the region of sexual life, owing to the wide oscillations in the intensity of sexual needs and the complications of the conditions necessary in order to bring about a sexual trauma. Here the cathartic method does all that can be asked of it, for the physician cannot set himself the task of altering a constitution such as the hysterical one. He must content himself with getting rid of the troubles to which such a constitution is inclined and which may arise from it with the conjunction of external circumstances. He will feel satisfied if the patient regains her working capacity. Moreover, he is not without consolation for the future when he considers the possibility of a relapse. He is aware of the principal feature in the aetiology of the neuroses - that their genesis is as a rule overdetermined, that several factors must come together to produce this result; and he may hope that this convergence will not be repeated at once, even though a few individual aetiological factors remain operative.

It might be objected that, in cases of hysteria like this, in which the illness has run its course, the residual symptoms in any case pass away spontaneously. It may be said in reply, however, that a spontaneous cure of this kind is very often neither rapid nor complete enough and that it can be assisted to an extraordinary degree by our therapeutic intervention. We may readily leave it for the moment as an unresolved question whether by means of the cathartic therapy we cure only what is capable of spontaneous cure or sometimes also what would not have been cleared up spontaneously.

(4) Where we meet with an acute hysteria, a case which is passing through the period of the most active production of hysterical symptoms and in which the ego is being constantly overwhelmed by the products of the illness (i.e. during a hysterical psychosis), even the cathartic method will make little change in the appearance and course of the disorder. In such circumstances we find ourselves in the same position as regards the neurosis as a physician faced by an acute infectious disease. The aetiological factors have performed their work sufficiently, at a time which has now passed and is beyond the reach of any influence; and now, after the period of incubation has elapsed, they have become manifest. The illness cannot be broken off short. We must wait for it to run its course and in the mean time make the patient's circumstances as favourable as possible. If, during an acute period like this, we get rid of the products of the illness, the freshly generated hysterical symptoms, we must also be prepared to find that those that have been got rid of will promptly be replaced by others. The physician will not be spared the depressing feeling of being faced by a Sisyphean task. The immense expenditure of labour, and the dissatisfaction of the patient's family, to whom the inevitable length of an acute neurosis is not likely to be as familiar as the analogous case of an acute infectious disease - these and other difficulties will probably make a systematic application of the cathartic method as a rule impossible in any given case. Nevertheless, it remains a matter for serious consideration whether it may not be true that even in an acute hysteria the regular clearing up of the products of the illness exercises a curative influence, by supporting the patient's normal ego which is engaged in the work of defence, and by preserving it from being overwhelmed and falling into a psychosis and even perhaps into a permanent state of confusion.

What the cathartic method is able to accomplish even in acute hysteria, and how it even restricts the fresh production of pathological symptoms in a manner that is of practical importance, is quite clearly revealed by the case history of Anna O., in which Breuer first learnt to employ this psychotherapeutic procedure.

(5) Where it is a question of hysterias which run a chronic course, accompanied by a moderate but constant production of hysterical symptoms, we find the strongest reason for regretting our lack of a therapy which is effective causally, but we also have most ground for the appreciation of the value of the cathartic procedure as a *symptomatic* therapy. In such cases we have to do with the mischief produced by an aetiology that persists chronically. Everything depends on reinforcing the patient's nervous system in its capacity to resist; and we must reflect that the existence of a hysterical symptom means a weakening of the resistance of that nervous system and represents a factor predisposing to hysteria. As can be seen from the mechanism of monosymptomatic hysteria, a new hysterical symptom is most easily formed in connection with, and on the analogy of, one that is already present. The point at which a symptom has already broken through once (see [p. 181](#)) forms a weak spot at which it will break through again the next time. A psychical group that has once been split off plays the part of a 'provoking' crystal from which a crystallization which would otherwise not have occurred will start with the greatest facility. To get rid of the symptoms which are already present, to undo the psychical changes which underlie them, is to give back to patients the whole amount of their capacity for resistance, so that they can successfully withstand the effects of the noxious agency. A very great deal can be done for such patients by means of prolonged supervision and occasional 'chimney-sweeping' ([p. 29](#)).

(6) It remains for me to mention the apparent contradiction between the admission that not all hysterical symptoms are psychogenic and the assertion that they can all be got rid of by a psychotherapeutic procedure. The solution lies in the fact that some of these non-psychogenic symptoms (stigmata, for instance) are, it is true, indications of illness, but cannot be described as ailments; and consequently it is not of practical importance if they persist after the successful treatment of the illness. As regards other such symptoms, it seems to be the case that in some roundabout way they are carried off along with the psychogenic symptoms, just as, perhaps, in some roundabout way they are after all dependent on a psychical causation.

I must now consider the difficulties and disadvantages of our therapeutic procedure, so far as they do not become obvious to everyone from the case histories reported above or from the remarks on the technique of the method which follow later. I will enumerate and indicate these difficulties rather than elaborate them.

The procedure is laborious and time-consuming for the physician. It presupposes great interest in psychological happenings, but personal concern for the patients as well. I cannot imagine bringing myself to delve into the psychical mechanism of a hysteria in anyone who struck me as low-minded and repellent, and who, on closer acquaintance, would not be capable of arousing human sympathy; whereas I can keep the treatment of a tabetic or rheumatic patient apart from personal approval of this kind. The demands made on the patient are not less. The procedure is not applicable at all below a certain level of intelligence, and it is made very much more difficult by any trace of feebleness of mind. The complete consent and complete attention of the patients are needed, but above all their confidence, since the analysis invariably leads to the disclosure of the most intimate and secret psychical events. A good number of the patients who would be suitable for this form of treatment abandon the doctor as soon as the suspicion begins to dawn on them of the direction in which the investigation is leading. For patients such as these the doctor has remained a stranger. With others, who have decided to put themselves in his hands and place their confidence in him - a step which in other such situations is only taken voluntarily and never at the doctor's request - with these other patients, I say, it is almost inevitable that their personal relation to him will force itself, for a time at least, unduly into the foreground. It seems, indeed, as though an influence of this kind on the part of the doctor is a *sine qua non* to a solution of the problem. I do not think any essential difference is made in this respect whether hypnosis can be used or whether it has to be by-passed and replaced by something else. But reason demands that we should emphasize the fact that these drawbacks, though they are inseparable from our procedure, cannot be laid at its door. On the contrary, it is quite clear that they are based on the predetermining conditions of the neuroses that are to be cured and that they must attach to any medical activity which involves intense preoccupation with the patient and leads to a psychical change in him. I have not been able to attribute any deleterious effects or danger to the employment of hypnosis, though I made copious use of it in some of my cases. Where I caused damage, the reasons lay elsewhere and deeper. If I survey my therapeutic efforts during the last few years since the communications made by my honoured teacher and friend Josef Breuer showed me the use of the cathartic method, I believe that in spite of everything, I have done much more, and more frequent, good than harm and have accomplished some things which no other therapeutic procedure could have achieved. It has on the whole, as the 'Preliminary Communication' put it, brought 'considerable therapeutic advantages'.

There is one other advantage in the use of this procedure which I must emphasize. I know of no better way of getting to understand a severe case of complicated neurosis with a greater or lesser admixture of hysteria than by submitting it to an analysis by Breuer's method. The first thing that happens is the disappearance of whatever exhibits a hysterical mechanism. In the meantime I have learnt in the course of the analysis to interpret the residual phenomena and to trace their aetiology; and in this way I have secured a firm basis for deciding which of the weapons in the therapeutic armoury against the neuroses is indicated in the case concerned. When I reflect on the difference that I usually find between my judgement on a case of neurosis *before* and *after* an analysis of this kind, I am almost inclined to regard an analysis as essential for the understanding of a neurotic illness. Moreover, I have adopted the habit of combining cathartic psychotherapy with a rest-cure which can, if need be, be extended into a complete treatment of feeding-up on Weir Mitchell lines. This gives me the advantage of being able on the one hand to avoid the very disturbing introduction of new psychical impressions during a psychotherapy, and on the other hand to remove the boredom of a rest-cure, in which the patients not infrequently fall into the habit of harmful day-dreaming. It might be expected that the often very considerable psychical work imposed on the patients during a cathartic treatment, and the excitations resulting from the reproduction of traumatic experiences, would run counter to the intentions of the Weir Mitchell rest cure and would hinder the successes which we are accustomed to see it bring about. But the opposite is in fact the case. A combination such as this between the Breuer and Weir Mitchell procedures produces all the physical improvement that we expect from the latter, as well as having a far-reaching psychical influence such as never results from a rest-cure without psychotherapy.

(2)

I will now return to my earlier remark that in my attempts to apply Breuer's method more extensively I came upon the difficulty that a number of patients could not be hypnotized, although their diagnosis was one of hysteria and it seemed probable that the psychical mechanism described by us operated in them. I needed hypnosis to extend their memory in order to find the pathogenic recollections which were not present in their ordinary consciousness. I was obliged therefore either to give up the idea of treating such patients or to endeavour to bring about this extension in some other way.

I was able as little as anyone else to explain why it is that one person can be hypnotized and another not, and thus I could not adopt a causal method of meeting the difficulty. I noticed, however, that in some patients the obstacle lay still further back: they refused even any *attempt* at hypnosis. The idea then occurred to me one day that the two cases might be identical and that both might signify an unwillingness; that people who were not hypnotizable were people who had a psychical objection to hypnosis, whether their objection was expressed as unwillingness or not. I am not clear in my mind whether I can maintain this view.

The problem was, however, how to by-pass hypnosis and yet obtain the pathogenic recollections. This I succeeded in doing in the following manner.

When, at our first interview, I asked my patients if they remembered what had originally occasioned the symptom concerned, in some cases they said they knew nothing of it, while in others they brought forward something which they described as an obscure recollection and could not pursue further. If, following the example of Bernheim when he awoke in his patients impressions from their somnambulistic state which had ostensibly been forgotten (cf. p. 98 f.), I now became insistent - if I assured them that they *did* know it, that it would occur to their minds, - then, in the first cases, something did actually occur to them, and, in the others, their memory went a step further. After this I became still more insistent; I told the patients to lie down and deliberately close their eyes in order to 'concentrate' - all of which had at least some resemblance to hypnosis. I then found that without any hypnosis new recollections emerged which went further back and which probably related to our topic. Experiences like this made me think that it would in fact be possible for the pathogenic groups of ideas, that were after all certainly present, to be brought to light by mere insistence; and since this insistence involved effort on my part and so suggested the idea that I had to overcome a resistance, the situation led me at once to the theory that *by means of my psychical work I had to overcome a psychical force in the patients which was opposed to the pathogenic ideas becoming conscious (being remembered)*. A new understanding seemed to open before my eyes when it occurred to me that this must no doubt be the same psychical force that had played a part in the generating of the hysterical symptom and had at that time prevented the pathogenic idea from becoming conscious. What kind of force could one suppose was operative here, and what motive could have put it into operation? I could easily form an opinion on this. For I already had at my disposal a few completed analyses in which I had come to know examples of ideas that were pathogenic, and had been forgotten and put out of consciousness. From these I recognized a universal characteristic of such ideas: they were all of a distressing nature, calculated to arouse the affects of shame, of self-reproach and of psychical pain, and the feeling of being harmed; they were all of a kind that one would prefer not to have experienced, that one would rather forget. From all this there arose, as it were automatically, the thought of *defence*. It has indeed been generally admitted by psychologists that the acceptance of a new idea (acceptance in the sense of believing or of recognizing as real) is dependent on the nature and trend of the ideas already united in the ego, and they have invented special technical names for this process of censorship to which the new arrival must submit. The patient's ego had been approached by an idea which proved to be incompatible, which provoked on the part of the ego a repelling force of which the purpose was defence against this incompatible idea. This defence was in fact successful. The idea in question was forced out of consciousness and out of memory. The psychical trace of it was apparently lost to view. Nevertheless that trace must be there. If I endeavoured to direct the patient's attention to it, I became aware, in the form of *resistance*, of the same force as had shown itself in the form of *repulsion* when the symptom was generated. If, now, I could make it appear probable that the idea had become pathogenic precisely as a result of its expulsion and repression, the chain would seem complete. In several of the discussions on our case histories, and in a short paper on 'The Neuro-Psychoses of Defence' (1894a), I have attempted to sketch out the psychological hypotheses by the help of which this causal connection - the fact of conversion - can be demonstrated.

Thus a psychical force, aversion on the part of the ego, had originally driven the pathogenic idea out of association and was now opposing its return to memory. The hysterical patient's 'not knowing' was in fact a 'not wanting to know' - a not wanting which might be to a greater or less extent conscious. The task of the therapist, therefore, lies in overcoming by his psychical work this resistance to association. He does this in the first place by 'insisting', by making use of psychical compulsion to direct the patients' attention to the ideational traces of which he is in search. His efforts, however, are not exhausted by this, but, as I shall show, they take on other forms in the course of an analysis and call in other psychical forces to assist them.

I must dwell on the question of insistence a little longer, Simple assurances such as 'of course you know it', 'tell me all the same', 'you'll think of it in a moment' do not carry us very far. Even with patients in a state of 'concentration' the thread breaks off after a few sentences. It should not be forgotten, however, that it is always a question here of a *quantitative* comparison, of a struggle between motive forces of different degrees of strength or intensity. Insistence on the part of a strange doctor who is unfamiliar with what is happening is not powerful enough to deal with the resistance to association in a serious case of hysteria. We must think of stronger means.

In these circumstances I make use in the first instance of a small technical device. I inform the patient that, a moment later, I shall apply pressure to his forehead, and I assure him that, all the time the pressure lasts, he will see before him a recollection in the form of a picture or will have it in his thoughts in the form of an idea occurring to him; and I pledge him to communicate this picture or idea to me, whatever it may be. He is not to keep it to himself because he may happen to think it is not, or because it would be too disagreeable for him to say it. There is to be no criticism of it, no reticence, either for emotional reasons or because it is judged unimportant. Only in this manner can we find what we are in search of, but in this manner we shall find it infallibly. Having said this, I press for a few seconds on the forehead of the patient as he lies in front of me; I then leave go and ask quietly, as though there were no question of a disappointment: 'What did you see?' or 'What occurred to you?'

This procedure has taught me much and has also invariably achieved its aim. To-day I can no longer do without it. I am of course aware that a pressure on the forehead like this could be replaced by any other signal or by some other exercise of physical influence on the patient; but since the patient is lying in front of me, pressure on his forehead, or taking his head between my two hands, seems to be the most convenient way of applying suggestion for the purpose I have in view. It would be possible for me to say by way of explaining the efficacy of this device that it corresponded to a 'momentarily intensified hypnosis'; but the mechanism of hypnosis is so puzzling to me that I would rather not make use of it as an explanation. I am rather of opinion that the advantage of the procedure lies in the fact that by means of it I dissociate the patient's attention from his conscious searching and reflecting - from everything, in short, on which he can employ his will - in the same sort of way in which this is effected by staring into a crystal ball, and so on. The conclusion which I draw from the fact that what I am looking for always appears under the pressure of my hand is as follows. The pathogenic idea which has ostensibly been forgotten is always lying ready 'close at hand' and can be reached by associations that are easily accessible. It is merely a question of getting some obstacle out of the way. This obstacle seems once again to be the subject's will, and different people can learn with different degrees of ease to free themselves from their intentional thinking and to adopt an attitude of completely objective observation towards the psychical processes taking place in them.

What emerges under the pressure of my hand is not always a 'forgotten' recollection; it is only in the rarest cases that the actual pathogenic recollections lie so easily to hand on the surface. It is much more frequent for an idea to emerge which is an intermediate link in the chain of associations between the idea from which we start and the pathogenic idea which we are in search of; or it may be an idea which forms the starting point of a new series of thoughts and recollections at the end of which the pathogenic idea will be found. It is true that where this happens my pressure has not revealed the pathogenic idea - which would in any case be incomprehensible, torn from its context and without being led up to - but it has pointed the way to it and has shown the direction in which further investigation is to be made. The idea that is first provoked by the pressure may in such cases be a familiar recollection which has never been repressed. If on our way to the pathogenic idea the thread is broken off once more, it only needs a repetition of the procedure, of the pressure, to give us fresh bearings and a fresh starting-point.

On yet other occasions the pressure of the hand provokes a memory which is familiar in itself to the patient, but the appearance of which astonishes him because he has forgotten its relation to the idea from which we started. This relation is then confirmed in the further course of the analysis. All these consequences of the pressure give one a deceptive impression of there being a superior intelligence outside the patient's consciousness which keeps a large amount of psychical material arranged for particular purposes and has fixed a planned order for its return to consciousness. I suspect, however, that this unconscious second intelligence is no more than an appearance.

In every fairly complicated analysis the work is carried on by the repeated, indeed continuous, use of this procedure of pressure on the forehead. Sometimes this procedure, starting from where the patient's waking retrospection breaks off, points the further path through memories of which he has remained aware; sometimes it draws attention to connections which have been forgotten; sometimes it calls up and arranges recollections which have been withdrawn from association for many years but which can still be recognized as recollections; and sometimes, finally, as the climax of its achievement in the way of reproductive thinking, it causes thoughts to emerge which the patient will never recognize as his own, which he never *remembers*, although he admits that the context calls for them inexorably, and while he becomes convinced that it is precisely these ideas that are leading to the conclusion of the analysis and the removal of his symptoms.

I will try to enumerate a few instances of the excellent results brought about by this technical procedure.

I treated a girl suffering from an intolerable *tussis nervosa* which had dragged on for six years. It obviously drew nourishment from every common catarrh, but must nevertheless have had strong psychical motives. All other kinds of therapy had long proved impotent against it. I therefore tried to remove the symptom by means of psychical analysis. All she knew was that her nervous cough began when, at the age of fourteen, she was boarding with an aunt. She maintained that she knew nothing of any mental agitations at that time and did not believe that there was any motive for her complaint. Under the pressure of my hand she first of all remembered a big dog. She then recognized the picture in her memory: it was a dog of her aunt's which became attached to her, followed her about everywhere, and so on. And it now occurred to her, without further prompting, that this dog died, that the children gave it a solemn burial and that her cough started on the way back from the funeral. I asked why, but had once more to call in the help of a pressure. The thought then came to her: 'Now I am quite alone in the world. No one here loves me. This creature was my only friend, and now I have lost him.' She continued her story. 'The cough disappeared when I left my aunt's, but it came on again eighteen months later.' 'Why was that?' 'I don't know.' I pressed again. She recalled the news of her uncle's death, when the cough started again, and also recalled having a similar train of thought. Her uncle seems to have been the only member of the family who had shown any feeling for her, who had loved her. Here, then, was the pathogenic idea. No one loved her, they preferred everyone else to her, she, did not deserve to be loved, and so on. But there was something attaching to the idea of 'love' which there was a strong resistance to her telling me. The analysis broke off before this was cleared up.

Some time ago I was asked to relieve an elderly lady of her attacks of anxiety, though judging by her traits of character she was scarcely suitable for treatment of this kind. Since her menopause she had become excessively pious, and she used to receive me at each visit armed with a small ivory crucifix concealed in her hand, as though I were the Evil One. Her anxiety attacks, which were of a hysterical character, went back to her early girlhood and, according to her, originated from the use of a preparation of iodine intended to reduce a moderate swelling of her thyroid gland. I naturally rejected this derivation and tried to find another instead of it which would harmonize better with my views on the aetiology of the neuroses. I asked her first for an impression from her youth which stood in a causal relation to her anxiety attacks, and, under the pressure of my hand, a memory emerged of her reading what is known as an 'edifying' book, in which there occurred a mention, in a sufficiently pious strain, of the sexual processes. The passage in question made an impression on the girl which was quite the reverse of the author's intention: she burst into tears and flung the book away. This was *before* her first anxiety attack. A second pressure on the patient's forehead conjured up a further reminiscence - the recollection of a tutor of her brothers who had manifested a great admiration for her and towards whom she herself had had feelings of some warmth. This recollection culminated in the reproduction of an evening in her parents' house when they had all sat round the table with the young man and had enjoyed themselves immensely in an entertaining conversation. During the night following that evening she was woken up by her first anxiety attack which, it is safe to say, had more to do with a repudiation of a sensual impulse than with any contemporary doses of iodine. - What prospect should I have had by any other method of revealing such a connection, against her own views and assertions, in this recalcitrant patient who was so prejudiced against me and every form of mundane therapy?

Another example concerns a young, happily-married woman. As long ago as in her early girlhood she used for some time to be found every morning in a stuporose condition, with her limbs rigid, her mouth open and her tongue protruding; and now once again she was suffering, on waking, from attacks which were similar though not so severe. Since deep hypnosis turned out not to be obtainable, I began to investigate while she was in a state of concentration. At my first pressure I assured her that she would see something that was directly related to the causes of her condition in her childhood. She was quiet and co-operative. She saw once more the house in which she had spent her early girlhood, her own room, the position of her bed, her grandmother, who had lived with them at that time, and one of her governesses of whom she had been very fond. A number of small scenes, all of them unimportant, which took place in these rooms and between these people followed one after the other; they were concluded by the departure of the governess, who left in order to get married. I could make nothing at all of these reminiscences; I could not establish any relation between them and the aetiology of the attacks. Various circumstances showed, however, that they belonged to the same period at which the attacks first appeared. But before I was able to proceed with the analysis I had occasion to talk to a colleague who in former years had been the family doctor of my patient's parents. He gave me the following information. At the time at which he was treating the girl, who was approaching maturity and very well developed physically, for her first attacks, he was struck by the excessive affectionateness of the relation between her and the governess who was at that time in the house. He became suspicious and induced the grandmother to keep an eye on this relationship. After a short time the old lady was able to report to him that the governess was in the habit of visiting the child in bed at night and that after such nights the child was invariably found next morning in an attack. They did not hesitate after this to arrange for the silent removal of this corrupter of youth. The children and even the mother were encouraged to believe that the governess had left in order to get married. - My therapy, which was immediately successful, consisted in giving the young woman the information I had received.

The revelations which one obtains through the procedure of pressing occasionally appear in a very remarkable form and in circumstances which make the assumption of there being an unconscious intelligence even more tempting. Thus I remember a lady who had suffered for many years from obsessions and phobias and who referred me to her childhood for the genesis of her illness but was also quite unable to say what might be to blame for it. She was frank and intelligent and she put up only a remarkably small conscious resistance. (I may remark in parenthesis that the psychical mechanism of obsessions has a very great deal of internal kinship with hysterical symptoms and that the technique of analysis is the same for both of them.) When I asked this lady whether she had seen anything or had any recollection under the pressure of my hand, she replied: 'Neither the one nor the other, but a word has suddenly occurred to me.' 'A single word?' 'Yes, but it sounds too silly.' 'Say it all the same.' 'Concierge.' 'Nothing else?' 'No.' I pressed a second time and once more an isolated word shot through her mind: 'Night-gown.' I saw now that this was a new sort of method of answering, and by pressing repeatedly I brought out what seemed to be a meaningless series of words: 'Concierge' - 'night-gown' - 'bed' - 'town' - 'farm-cart.' 'What does all this mean?' I asked. She reflected for a moment and the following thought occurred to her: 'It must be the story that has just come into my head. When I was ten years old and my next elder sister was twelve, she went raving mad one night and had to be tied down and taken into the town on a farm-cart. I remember perfectly that it was the concierge who overpowered her and afterwards went with her to the asylum as well.' We pursued this method of investigation and our oracle produced another series of words, which, though we were not able to interpret all of them, made it possible to continue this story and lead on from it to another one. Soon, moreover, the meaning of this reminiscence became clear. Her sister's illness had made such a deep impression on her because the two of them shared a secret; they slept in one room and on a particular night they had both been subjected to sexual assaults by a certain man. The mention of this sexual trauma in the patient's childhood revealed not only the origin of her first obsessions but also the trauma which subsequently produced the pathogenic effects.

The peculiarity of this case lay only in the emergence of isolated key-words which we had to work into sentences; for the appearance of disconnectedness and irrelevance which characterized the words emitted in this oracular fashion applies equally to the complete ideas and scenes which are normally produced under my pressure. When these are followed up, it invariably turns out that the apparently disconnected reminiscences are closely linked in thought and that they lead quite straight to the pathogenic factor we are looking for. For this reason I am glad to recall a case of analysis in which my confidence in the products of pressure were first put to a hard test but afterwards brilliantly justified.

A very intelligent and apparently happy young married woman had consulted me about an obstinate pain in her abdomen which was resistant to treatment. I recognized that the pain was situated in the abdominal wall and must be referred to palpable muscular indurations, and I ordered local treatment. Some months later I saw the patient again and she said to me: 'The pain I had then passed off after the treatment you recommended, and it stayed away for a long time; but now it has come back in a nervous form. I know that is so, because I no longer have it, as I used to, when I make certain movements, but only at particular times - for instance, when I wake up in the morning and when I am agitated in certain ways.' The lady's diagnosis was quite correct. It was now a question of finding out the cause of the pain, and she could not help me about this while she was in an uninfluenced state. When I asked her, in concentration and under the pressure of my hand, whether anything occurred to her or whether she saw anything, she decided in favour of seeing and began to describe her visual pictures. She saw something like a sun with rays, which I naturally took to be a phosphene, produced by pressure on the eyes. I expected that something more serviceable would follow. But she went on: 'Stars of a curious pale blue light, like moon light' and so on, all of which I took to be no more than flickering, flashes and bright specks before her eyes. I was already prepared to regard this experiment as a failure and I was wondering how I could make an inconspicuous retreat from the affair, when my attention was attracted by one of the phenomena which she described. She saw a large black cross, leaning over, which had round its edges the same shimmer of light with which all her other pictures had shone, and on whose cross-beam a small flame flickered. Clearly there could no longer be any question of a phosphene here. I now listened carefully. Quantities of pictures appeared bathed in the same light, curious signs looking rather like Sanskrit; figures like triangles, among them a large triangle; the cross once more. . . . This time I suspected an allegorical meaning and asked what the cross could be. 'It probably means pain,' she replied. I objected that by 'cross' one usually meant a moral burden. What lay concealed behind the pain? She could not say, and went on with her visions: a sun with golden rays. And this she was also able to interpret. 'It's God, the *primaeval* force.' Then came a gigantic lizard which regarded her enquiringly but not alarmingly. Then a heap of snakes. Then once more a sun, but with mild, silver rays; and in front of her, between her and this source of light, a grating which hid the centre of the sun from her. I had known for some time that what I had to deal with were allegories and at once asked the meaning of this last picture. She answered without hesitation: 'The sun is perfection, the ideal, and the grating represents my weaknesses and faults which stand between me and the ideal.' 'Are you reproaching yourself, then? Are you dissatisfied with yourself?' 'Yes indeed.' 'Since when?' 'Since I have been a member of the Theosophical Society and have been reading its publications. I always had a low opinion of myself.' 'What has made the strongest impression on you recently?' 'A translation from the Sanskrit which is just now coming out in instalments.' A minute later I was being initiated into her mental struggles and her self-reproaches, and was hearing about a small episode which gave rise to a self-reproach - an occasion on which what had previously been an organic pain now for the first time appeared as the consequence of the conversion of an excitation. The pictures which I had first taken for phosphenes were symbols of trains of thought influenced by the occult and were perhaps actually emblems from the title-pages of occult books.

Hitherto I have been so warm in my praises of the achievements of pressure as an auxiliary procedure, and I have the whole time so greatly neglected the aspect of defence or resistance, that I may no doubt have created an impression that this little device has put us in a position to master the psychological obstacles to a cathartic treatment. But to believe this would be to make a serious mistake. Gains of this kind, so far as I can see, are not to be looked for in treatment. Here, as elsewhere, a large change requires a large amount of work. The procedure by pressure is no more than a trick for temporarily taking unawares an ego which is eager for defence. In all fairly serious cases the ego recalls its aims once more and proceeds with its resistance.

I must mention the different forms in which this resistance appears. One is that, as a rule, the pressure procedure fails on the first or second occasion. The patient then declares, very disappointedly: 'I expected something would occur to me, but all I thought was how tensely I was expecting it. Nothing came.' The fact of the patient putting himself on his guard like this does not yet amount to an obstacle. We can say in reply: 'It's precisely because you were too curious; it will work next time.' And in fact it does work. It is remarkable how often patients, even the most docile and intelligent, can completely forget their undertaking, though they had agreed to it beforehand. They promised to say whatever occurred to them under the pressure of my hand, irrespectively of whether it seemed to them relevant or not, and of whether it was agreeable to them to say it or not - to say it, that is, without selecting and without being influenced by criticism or affect. But they do not keep this promise; it is evidently beyond their strength to do so. The work keeps on coming to a stop and they keep on maintaining that this time nothing has occurred to them. We must not believe what they say, we must always assume, and tell them, too, that they have kept something back because they thought it unimportant or found it distressing. We must insist on this, we must repeat the pressure and represent ourselves as infallible, till at last we are really told something. The patient then adds: 'I could have told you that the first time.' 'Why didn't you say it?' 'I couldn't believe it could be that. It was only when it came back every time that I made up my mind to say it.' Or else: 'I hoped it wouldn't be that of all things. I could well do without saying that. It was only when it refused to be repressed that I saw I shouldn't be let off.' Thus after the event the patient betrays the motives for a resistance which he refused to admit to begin with. He is evidently quite unable to do anything but put up resistance.

This resistance often conceals itself behind some remarkable excuses. 'My mind is distracted to-day; the clock (or the piano in the next room) is disturbing me.' I have learned to answer such remarks: 'Not at all. You have at this moment come up against something that you had rather not say. It won't do any good. Go on thinking about it.' The longer the pause between my hand-pressure and the patient's beginning to speak, the more suspicious I become and the more it is to be feared that the patient is re-arranging what has occurred to him and is mutilating it in his reproduction of it. A most important piece of information is often announced as being a redundant accessory, like an opera prince disguised as a beggar. 'Something has occurred to me now, but it has nothing to do with the subject. I'm only saying it because you want to know every thing.' Accompanying words such as these usually introduce the long-sought solution. I always prick up my ears when I hear a patient speak so disparagingly of something that has occurred to him. For it is an indication that defence has been successful if the pathogenic ideas seem, when they re-emerge, to have so little importance. From this we can infer in what the process of defence consisted: it consisted in turning a strong idea into a weak one, in robbing it of its affect.

A pathogenic recollection is thus recognizable, among other things, by the fact that the patient describes it as unimportant and nevertheless only utters it under resistance. There are cases, too, in which the patient tries to disown it even after its return. 'Something has occurred to me now, but you obviously put it into my head.' Or, 'I know what you expect me to answer. Of course you believe I've thought this or that.' A particularly clever method of disavowal lies in saying: 'Something has occurred to me now, it's true, but it seems to me as if I'd put it in deliberately. It doesn't seem to be a reproduced thought at all.' In all such cases, I remain unshakeably firm. I avoid entering into any of these distinctions but explain to the patient that they are only forms of his resistance and pretexts raised by it against reproducing this particular memory, which we must recognize in spite of all this.

When memories return in the form of pictures our task is in general easier than when they return as thoughts. Hysterical patients, who are as a rule of a 'visual' type, do not make such difficulties for the analyst as those with obsessions.

Once a picture has emerged from the patient's memory, we may hear him say that it becomes fragmentary and obscure in proportion as he proceeds with his description of it. *The patient is, as it were, getting rid of it by turning it into words.* We go on to examine the memory picture itself in order to discover the direction in which our work is to proceed. 'Look at the picture once more. Has it disappeared?' 'Most of it, yes, but I still see this detail.' 'Then this residue must still mean something. Either you will see something new in addition to it, or something will occur to you in connection with it.' When this work has been accomplished, the patient's field of vision is once more free and we can conjure up another picture. On other occasions, however, a picture of this kind will remain obstinately before the patient's inward eye, in spite of his having described it; and this is an indication to me that he still has something important to tell me about the topic of the picture. As soon as this has been done the picture vanishes, like a ghost that has been laid.

It is of course of great importance for the progress of the analysis that one should always turn out to be in the right *vis-à-vis* the patient, otherwise one would always be dependent on what he chose to tell one. It is therefore consoling to know that the pressure technique in fact never fails, apart from a single case, which I shall have to discuss later but of which I can at once say that it corresponds to a particular motive for resistance. It can of course happen that one makes use of the procedure in circumstances in which there is nothing for it to reveal. For instance, we may ask for the further aetiology of a symptom when we already have it completely before us, or we may investigate a psychical genealogy of a symptom, such as a pain, which is in fact a somatic one. In such cases the patient will equally assert that nothing has occurred to him and this time he will be in the right. We can avoid doing the patient an injustice if we make it a quite general rule all through the analysis to keep an eye on his facial expression as he lies quietly before us. We can then learn to distinguish without any difficulty the restful state of mind that accompanies the real absence of a recollection from the tension and signs of emotion with which he tries to disavow the emerging recollection, in obedience to defence. Moreover, experiences like these make it possible also to use the pressure technique for purposes of differential diagnosis.

Thus even with the assistance of the pressure technique the work is by no means easy. The one advantage that we gain is of learning from the results of this procedure the direction in which we have to conduct our enquiries and the things that we have to insist upon to the patient. With some cases this suffices. The principal point is that I should guess the secret and tell it to the patient straight out; and he is then as a rule obliged to abandon his rejection of it. In other cases more is required. The patient's persisting resistance is indicated by the fact that connections are broken, solutions fail to appear, the pictures are recalled indistinctly and incompletely. Looking back from a later period of an analysis to an earlier one, we are often astonished to realize in what a mutilated manner all the ideas and scenes emerged which we extracted from the patient by the procedure of pressing. Precisely the essential elements of the picture were missing - its relation to himself or to the main contents of his thoughts - and that is why it remained unintelligible.

I will give one or two examples of the way in which a censoring of this kind operates when pathogenic recollections first emerge. For instance, the patient sees the upper part of a woman's body with the dress not properly fastened - out of carelessness, it seems. It is not until much later that he fits a head to this torso and thus reveals a particular person and his relation to her. Or he brings up a reminiscence from his childhood of two boys. What they look like is quite obscure to him, but they are said to have been guilty of some misdeed. It is not until many months later and after the analysis has made great advances that he sees this reminiscence once more and recognizes himself in one of the children and his brother in the other.

What means have we at our disposal for overcoming this continual resistance? Few, but they include almost all those by which one man can ordinarily exert a psychical influence on another. In the first place, we must reflect that a psychical resistance, especially one that has been in force for a long time, can only be resolved slowly and by degrees, and we must wait patiently. In the next place, we may reckon on the intellectual interest which the patient begins to feel after working for a short time. By explaining things to him, by giving him information about the marvellous world of psychical processes into which we ourselves only gained insight by such analyses, we make him himself into a collaborator, induce him to regard himself with the objective interest of an investigator, and thus push back his resistance, resting as it does on an affective basis. But lastly - and this remains the strongest lever - we must endeavour, after we have discovered the motives for his defence, to deprive them of their value or even to replace them by more powerful ones. This no doubt is where it ceases to be possible to state psychotherapeutic activity in formulas. One works to the best of one's power, as an elucidator (where ignorance has given rise to fear), as a teacher, as the representative of a freer or superior view of the world, as a father confessor who gives absolution, as it were, by a continuance of his sympathy and respect after the confession has been made. One tries to give the patient human assistance, so far as this is allowed by the capacity of one's own personality and by the amount of sympathy that one can feel for the particular case. It is an essential precondition for such psychical activity that we should have more or less divined the nature of the case and the motives of the defence operating in it, and fortunately the technique of insistence and pressure takes us as far as this. The more such riddles we have already solved, the easier we may find it to guess a new one and the sooner we shall be able to start on the truly curative psychical work. For it is well to recognize this clearly: the patient only gets free from the hysterical symptom by reproducing the pathogenic impressions that caused it and by giving utterance to them with an expression of affect, and thus the therapeutic task *consists solely in inducing him to do so*; when once this task has been accomplished there is nothing left for the physician to correct or to remove. Whatever may be required for this purpose in the way of counter-suggestions has already been expended during the struggle against the resistance. The situation may be compared with the unlocking of a locked door, after which opening it by turning the handle offers no further difficulty.

Besides the intellectual motives which we mobilize to overcome the resistance, there is an affective factor, the personal influence of the physician, which we can seldom do without, and in a number of cases the latter alone is in a position to remove the resistance. The situation here is no different from what it is elsewhere in medicine and there is no therapeutic procedure of which one may say that it can do entirely without the co-operation of this personal factor.

(3)

In view of what I have said in the preceding section about the difficulties of my technique, which I have unsparingly exposed (I brought them together, incidentally, from the severest cases; things often turn out very much more conveniently) - in view of all this, then, everyone will no doubt feel inclined to ask whether it would not be more expedient, instead of putting up with all these troubles, to make a more energetic use of hypnosis or to restrict the use of the cathartic method to patients who can be put under deep hypnosis. As regards the latter proposal I should have to answer that in that case the number of suitable patients, so far as *my* skill is concerned, would dwindle far too much; and I would meet the first piece of advice with the suspicion that the forcible imposition of hypnosis might not spare us much resistance. My experiences on this point, oddly enough, have not been numerous, and I cannot, therefore, go beyond a suspicion. But where I have carried out a cathartic treatment under hypnosis instead of under concentration, I did not find that this diminished the work I had to do. Not long ago I completed a treatment of this kind in the course of which I caused a hysterical paralysis of the legs to clear up. The patient passed into a state which was very different psychically from waking and which was characterized physically by the fact that it was impossible for her to open her eyes or get up till I had called out to her: 'Now wake up!' None the less I have never come across greater resistance than in this case. I attached no importance to these physical signs, and towards the end of the treatment, which lasted ten months, they had ceased to be noticeable. But in spite of this the patient's state while we were working lost none of its psychical characteristics - the capacity she possessed for remembering unconscious material and her quite special relation to the figure of the physician. On the other hand, I have given an example in the case history of Frau Emmy von N. of a cathartic treatment in the deepest somnambulism in which resistance played scarcely any part. But it is also true that I learnt from that lady nothing whose telling might have called for any special overcoming of objections, nothing that she could not have told me even in a waking state, supposing we had been acquainted for some time and she had thought fairly highly of me. I never reached the true causes of her illness, which were no doubt identical with the causes of her relapse after my treatment (for this was my first attempt with this method); and the only occasion on which I happened to ask her for a reminiscence which involved an erotic element I found her just as reluctant and untrustworthy in what she told me as I did later with any of my non-somnambulist patients. I have already spoken in that lady's case history of the resistance which she put up even during somnambulism to other requests and suggestions of mine. I have become altogether sceptical about the value of hypnosis in facilitating cathartic treatments, since I have experienced instances in which during deep somnambulism there has been absolute *therapeutic* recalcitrance, where in other respects the patient has been perfectly obedient. I reported a case of this kind briefly on p. 90 n., and I could add others. I may admit, too, that this experience has corresponded pretty well to the requirement I insist upon that there shall be a quantitative relation between cause and effect in the psychical field as well.

In what I have hitherto said the idea of resistance has forced its way into the foreground. I have shown how, in the course of our therapeutic work, we have been led to the view that hysteria originates through the repression of an incompatible idea from a motive of defence. On this view, the repressed idea would persist as a memory trace that is weak (has little intensity), while the affect that is torn from it would be used for a somatic innervation. (That is, the excitation is 'converted'.) It would seem, then, that it is precisely through its repression that the idea becomes the cause of morbid symptoms - that is to say, becomes pathogenic. A hysteria exhibiting this psychological mechanism may be given the name of 'defence hysteria'.

Now both of us, Breuer and I, have repeatedly spoken of two other kinds of hysteria, for which we have introduced the terms 'hypnoid hysteria' and 'retention hysteria'. It was hypnoid hysteria which was the first of all to enter our field of study. I could not, indeed, find a better example of it than Breuer's first case, which stands at the head of our case histories. Breuer has put forward for such cases of hypnoid hysteria a psychological mechanism which is substantially different from that of defence by conversion. In his view what happens in hypnoid hysteria is that an idea becomes pathogenic because it has been received during a special psychological state and has from the first remained outside the ego. No psychological force has therefore been required in order to keep it apart from the ego and no resistance need be aroused if we introduce it into the ego with the help of mental activity during somnambulism. And Anna O.'s case history in fact shows no sign of any such resistance.

I regard this distinction as so important that, on the strength of it, I willingly adhere to this hypothesis of there being a hypnoid hysteria. Strangely enough, I have never in my own experience met with a genuine hypnoid hysteria. Any that I took in hand has turned into a defence hysteria. It is not, indeed, that I have never had to do with symptoms which demonstrably arose during dissociated states of consciousness and were obliged for that reason to remain excluded from the ego. This was sometimes so in my cases as well; but I was able to show afterwards that the so-called hypnoid state owed its separation to the fact that in it a psychological group had come into effect which had previously been split off by defence. In short, I am unable to suppress a suspicion that somewhere or other the roots of hypnoid and defence hysteria come together, and that there the primary factor is defence. But I can say nothing about this.

My judgement is for the moment equally uncertain as regards 'retention hysteria', in which the therapeutic work is supposed equally to proceed without resistance. I had a case which I looked upon as a typical retention hysteria and I rejoiced in the prospect of an easy and certain success. But this success did not occur, though the work was in fact easy. I therefore suspect, though once again subject to all the reserve which is proper to ignorance, that at the basis of retention hysteria, too, an element of defence is to be found which has forced the whole process in the direction of hysteria. It is to be hoped that fresh observations will soon decide whether I am running the risk of falling into one-sidedness and error in thus favouring an extension of the concept of defence to the whole of hysteria.

I have dealt so far with the difficulties and technique of the cathartic method, and I should like to add a few indications as to the form assumed by an analysis when this technique is adopted. For me this is a highly interesting subject, but I cannot expect it to arouse similar interest in others, who have not yet carried out an analysis of this kind. I shall, it is true, once more be talking about the technique, but this time it will be about inherent difficulties for which we cannot hold the patients responsible and which must be partly the same in a hypnoid or retention hysteria as in the defence hysterias which I have before my eyes as a model. I approach this last part of my exposition with the expectation that the psychical characteristics which will be revealed in it may one day acquire a certain value as raw material for the dynamics of ideation.

The first and most powerful impression made upon one during such an analysis is certainly that the pathogenic psychical material which has ostensibly been forgotten, which is not at the ego's disposal and which plays no part in association and memory, nevertheless in some fashion lies ready to hand and in correct and proper order. It is only a question of removing the resistances that bar the way to the material. In other respects this material is known, in the same way in which we are able to know anything; the correct connections between the separate ideas and between them and the non-pathogenic ones, which are frequently remembered, are in existence; they have been completed at some time and are stored up in the memory. The pathogenic psychical material appears to be the property of an intelligence which is not necessarily inferior to that of the normal ego. The appearance of a second personality is often presented in the most deceptive manner.

Whether this impression is justified, or whether in thinking this we are not dating back to the period of the illness an arrangement of the psychical material which in fact was made after recovery - these are questions which I should prefer not to discuss as yet, and not in these pages. The observations made during such analyses can in any case be most conveniently and clearly described if we regard them from the position that we are able to assume after recovery for the purpose of surveying the case as a whole.

As a rule, indeed, the situation is not as simple as we have represented it in particular cases - for instance, where there is one symptom only, which has arisen from one major trauma. We do not usually find a *single* hysterical symptom, but a number of them, partly independent of one another and partly linked together. We must not expect to meet with a *single* traumatic memory and a *single* pathogenic idea as its nucleus; we must be prepared for *successions* of *partial* traumas and *concatenations* of pathogenic trains of thought. A monosymptomatic traumatic hysteria is, as it were, an elementary organism, a unicellular creature, as compared with the complicated structure of such comparatively severe neuroses as we usually meet with.

The psychical material in such cases of hysteria presents itself as a structure in several dimensions which is stratified in at least three different ways. (I hope I shall presently be able to justify this pictorial mode of expression.) To begin with there is a nucleus consisting in memories of events or trains of thought in which the traumatic factor has culminated or the pathogenic idea has found its purest manifestation. Round this nucleus we find what is often an incredibly profuse amount of other mnemic material which has to be worked through in the analysis and which is, as we have said, arranged in a threefold order.

In the first place there is an unmistakable linear chronological order which obtains within each separate theme. As an example of this I will merely quote the arrangement of the material in Breuer's analysis of Anna O. Let us take the theme of becoming deaf, of not hearing. This was differentiated according to seven sets of determinants, and under each of these seven headings ten to over a hundred individual memories were collected in chronological series (p. 35). It was as though we were examining a dossier that had been kept in good order. The analysis of my patient Emmy von N. contained similar files of memories though they were not so fully enumerated and described. These files form a quite general feature of every analysis and their contents always emerge in a chronological order which is as infallibly trustworthy as the succession of days of the week or names of the month in a mentally normal person. They make the work of analysis more difficult by the peculiarity that, in reproducing the memories, they reverse the order in which these originated. The freshest and newest experience in the file appears first, as an outer cover, and last of all comes the experience with which the series in fact began.

I have described such groupings of similar memories into collections arranged in linear sequences (like a file of documents, a packet, etc.) as constituting 'themes'. These themes exhibit a second kind of arrangement. Each of them is - I can not express it in any other way - stratified concentrically round the pathogenic nucleus. It is not hard to say what produces this stratification, what diminishing or increasing magnitude is the basis of this arrangement. The contents of each particular stratum are characterized by an equal degree of resistance, and that degree increases in proportion as the strata are nearer to the nucleus. Thus there are zones within which there is all equal degree of modification of consciousness, and the different themes extend across these zones. The most peripheral strata contain the memories (or files), which, belonging to different themes, are easily remembered and have always been clearly conscious. The deeper we go the more difficult it becomes for the emerging memories to be recognized, till near the nucleus we come upon memories which the patient disavows even in reproducing them.

It is this peculiarity of the concentric stratification of the pathogenic psychical material which, as we shall hear, lends to the course of these analyses their characteristic features. A third kind of arrangement has still to be mentioned - the most important, but the one about which it is least easy to make any general statement. What I have in mind is an arrangement according to thought-content, the linkage made by a logical thread which reaches as far as the nucleus and tends to take an irregular and twisting path, different in every case. This arrangement has a dynamic character, in contrast to the morphological one of the two stratifications mentioned previously. While these two would be represented in a spatial diagram by a continuous line, curved or straight, the course of the logical chain would have to be indicated by a broken line which would pass along the most roundabout paths from the surface to the deepest layers and back, and yet would in general advance from the periphery to the central nucleus, touching at every intermediate halting-place - a line resembling the zig-zag line in the solution of a Knight's Move problem, which cuts across the squares in the diagram of the chess-board.

I must dwell for a moment longer on this last simile in order to emphasize a point in which it does not do justice to the characteristics of the subject of the comparison. The logical chain corresponds not only to a zig-zag, twisted line, but rather to a ramifying system of lines and more particularly to a converging one. It contains nodal points at which two or more threads meet and thereafter proceed as one; and as a rule several threads which run independently, or which are connected at various points by side-paths, debouch into the nucleus. To put this in other words, it is very remarkable how often a symptom is determined in several ways, is 'overdetermined'.

My attempt to demonstrate the organization of the pathogenic psychical material will be complete when I have introduced one more complication. For it can happen that there is more than one nucleus in the pathogenic material - if, for instance, we have to analyse a second outbreak of hysteria which has an aetiology of its own but is nevertheless connected with a first outbreak of acute hysteria which was got over years earlier. It is easy to imagine, if this is so, what additions there must be to the strata and paths of thought in order to establish a connection between the two pathogenic nuclei.

I shall now make one or two further remarks on the picture we have just arrived at of the organization of the pathogenic material. We have said that this material behaves like a foreign body, and that the treatment, too, works like the removal of a foreign body from the living tissue. We are now in a position to see where this comparison fails. A foreign body does not enter into any relation with the layers of tissue that surround it, although it modifies them and necessitates a reactive inflammation in them. Our pathogenic psychical group, on the other hand, does not admit of being cleanly extirpated from the ego. Its external strata pass over in every direction into portions of the normal ego; and, indeed, they belong to the latter just as much as to the pathogenic organization. In analysis the boundary between the two is fixed purely conventionally, now at one point, now at another, and in some places it cannot be laid down at all. The interior layers of the pathogenic organization are increasingly alien to the ego, but once more without there being any visible boundary at which the pathogenic material begins. In fact the pathogenic organization does not behave like a foreign body, but far more like an infiltrate. In this simile the resistance must be regarded as what is infiltrating. Nor does the treatment consist in extirpating something - psychotherapy is not able to do this for the present - but in causing the resistance to melt and in thus enabling the circulation to make its way into a region that has hitherto been cut off.

(I am making use here of a number of similes, all of which have only a very limited resemblance to my subject and which, moreover, are incompatible with one another. I am aware that this is so, and I am in no danger of over-estimating their value. But my purpose in using them is to throw light from different directions on a highly complicated topic which has never yet been represented. I shall therefore venture to continue in the following pages to introduce similes in the same manner, though I know this is not free from objection.)

If it were possible, after the case had been completely cleared up, to demonstrate the pathogenic material to a third person in what we now know is its complicated and multi-dimensional organization, we should rightly be asked how a camel like this got through the eye of the needle. For there is some justification for speaking of the 'defile' of consciousness. The term gains meaning and liveliness for a physician who carries out an analysis like this. Only a single memory at a time can enter ego-consciousness. A patient who is occupied in working through such a memory sees nothing of what is pushing after it and forgets what has already pushed its way through. If there are difficulties in the way of mastering this single pathogenic memory - as, for instance, if the patient does not relax his resistance against it, if he tries to repress or mutilate it - then the defile is, so to speak, blocked. The work is at a standstill, nothing more can appear, and the single memory which is in process of breaking through remains in front of the patient until he has taken it up into the breadth of his ego. The whole spatially-extended mass of psychogenic material is in this way drawn through a narrow cleft and thus arrives in consciousness cut up, as it were, into pieces or strips. It is the psychotherapist's business to put these together once more into the organization which he presumes to have existed. Anyone who has a craving for further similes may think at this point of a Chinese puzzle.

If we are faced with starting such an analysis, in which we have reason to expect an organization of pathogenic material like this, we shall be assisted by what experience has taught us, namely that *it is quite hopeless to try to penetrate directly to the nucleus of the pathogenic organization*. Even if we ourselves could guess it, the patient would not know what to do with the explanation offered to him and would not be psychologically changed by it.

There is nothing for it but to keep at first to the periphery of the psychical structure. We begin by getting the patient to tell us what he knows and remembers, while we are at the same time already directing his attention and overcoming his slighter resistances by the use of the pressure procedure. Whenever we have opened a new path by thus pressing on his forehead, we may expect him to advance some distance without fresh resistance.

After we have worked in this way for some time, the patient begins as a rule to co-operate with us. A great number of reminiscences now occur to him, without our having to question him or set him tasks. What we have done is to make a path to an inner stratum within which the patient now has spontaneously at his disposal material that has an equal degree of resistance attaching to it. It is best to allow him for a time to reproduce such material without being influenced. It is true that he himself is not in a position to uncover important connections, but he may be left to clear up material lying within the same stratum. The things that he brings up in this way often seem disconnected, but they offer material which will be given point when a connection is discovered later on.

Here we have in general to guard against two things. If we interfere with the patient in his reproduction of the ideas that pour in on him, we may 'bury' things that have to be freed later with a great deal of trouble. On the other hand we must not over-estimate the patient's unconscious 'intelligence' and leave the direction of the whole work to it. If I wanted to give a diagrammatic picture of our mode of operation, I might perhaps say that we ourselves undertake the opening up of inner strata, advancing *radially*, whereas the patient looks after the *peripheral* extension of the work.

Advances are brought about, as we know, by overcoming resistance in the manner already indicated. But before this, we have as a rule another task to perform. We must get hold of a piece of the logical thread, by whose guidance alone we may hope to penetrate to the interior. We cannot expect that the free communications made by the patient, the material from the most superficial strata, will make it easy for the analyst to recognize at what points the path leads into the depths or where he is to find the starting-points of the connections of thought of which he is in search. On the contrary, this is precisely what is carefully concealed; the account given by the patient sounds as if it were complete and self-contained. It is at first as though we were standing before a wall which shut out every prospect and prevents us from having any idea whether there is anything behind it, and if so, what.

But if we examine with a critical eye the account that the patient has given us without much trouble or resistance, we shall quite infallibly discover gaps and imperfections in it. At one point the train of thought will be visibly interrupted and patched up by the patient as best he may, with a turn of speech or an inadequate explanation; at another point we come upon a motive which would have to be described as a feeble one in a normal person. The patient will not recognize these deficiencies when his attention is drawn to them. But the physician will be right in looking behind the weak spots for an approach to the material in the deeper layers and in hoping that he will discover precisely there the connecting threads for which he is seeking with the pressure procedure. Accordingly, we say to the patient: 'You are mistaken; what you are putting forward can have nothing to do with the present subject. We must expect to come upon something else here, and this will occur to you under the pressure of my hand.'

For we may make the same demands for logical connection and sufficient motivation in a train of thought, even if it extends into the unconscious, from a hysterical patient as we should from a normal individual. It is not within the power of a neurosis to relax these relations. If the chains of ideas in neurotic and particularly in hysterical patients produce a different impression, if in them the relative intensity of different ideas seems inexplicable by psychological determinants alone, we have already found out the reason for this and can attribute it to *the existence of hidden unconscious motives*. We may thus suspect the presence of such secret motives wherever a breach of this kind in a train of thought is apparent or when the force ascribed by the patient to his motives goes far beyond the normal.

In carrying out this work we must of course keep free from the theoretical prejudice that we are dealing with the abnormal brains of '*dégénérés*' and '*déséquilibrés*',¹ who are at liberty, owing to a stigma, to throw overboard the common psychological laws that govern the connection of ideas and in whom one chance idea may become exaggeratedly intense for no motive and another may remain indestructible for no psychological reason. Experience shows that the contrary is true of hysteria. Once we have discovered the concealed motives, which have often remained unconscious, and have taken them into account, nothing that is puzzling or contrary to rule remains in hysterical connections of thought, any more than in normal ones.

In this way, then, by detecting lacunas in the patient's first description, lacunas which are often covered by 'false connections', we get hold of a piece of the logical thread at the periphery, and from this point on we clear a further path by the pressure technique.

In doing this, we very seldom succeed in making our way right into the interior along one and the same thread. As a rule it breaks off half-way: the pressure fails and either produces no result or one that cannot be clarified or carried further in spite of every effort. We soon learn, when this happens, to avoid the mistakes into which we might fall. The patient's facial expression must decide whether we have really come to an end, or whether this is an instance which requires no psychical elucidation, or whether what has brought the work to a standstill is excessive resistance. In the last case, if we cannot promptly overcome the resistance we may assume that we have followed the thread into a stratum which is for the time being still impenetrable. We drop it and take up another thread, which we may perhaps follow equally far. When we have arrived at this stratum along all the threads and have discovered the entanglements on account of which the separate threads could not be followed any further in isolation, we can think of attacking the resistance before us afresh.

¹ ['Degenerate' and 'unbalanced' persons.]

It is easy to imagine how complicated a work of this kind can become. We force our way into the internal strata, overcoming resistances all the time; we get to know the themes accumulated in one of these strata and the threads running through it, and we experiment how far we can advance with our present means and the knowledge we have acquired; we obtain preliminary information about the contents of the next strata by means of the pressure technique; we drop threads and pick them up again; we follow them as far as nodal points; we are constantly making up arrears; and every time that we pursue a file of memories we are led to some side-path, which nevertheless eventually joins up again. By this method we at last reach a point at which we can stop working in strata and can penetrate by a main path straight to the nucleus of the pathogenic organization. With this the struggle is won, though not yet ended. We must go back and take up the other threads and exhaust the material. But now the patient helps us energetically. His resistance is for the most part broken.

In these later stages of the work it is of use if we can guess the way in which things are connected up and tell the patient before we have uncovered it. If we have guessed right, the course of the analysis will be accelerated; but even a wrong hypothesis helps us on, by compelling the patient to take sides and by enticing him into energetic denials which betray his undoubted better knowledge.

We learn with astonishment from this that *we are not in a position to force anything on the patient about the things of which he is ostensibly ignorant or to influence the products of the analysis by arousing an expectation*. I have never once succeeded, by foretelling something, in altering or falsifying the reproduction of memories or the connection of events; for if I had, it would inevitably have been betrayed in the end by some contradiction in the material. If something turned out as I had foretold, it was invariably proved by a great number of unimpeachable reminiscences that I had done no more than guess right. We need not be afraid, therefore, of telling the patient what we think his next connection of thought is going to be. It will do no harm.

Another observation, which is constantly repeated, relates to the patient's spontaneous reproductions. It may be asserted that every single reminiscence which emerges during an analysis of this kind has significance. An intrusion of *irrelevant* mnemonic images (which happen in some way or other to be associated with the important ones) in fact never occurs. An exception which does not contradict this rule may be postulated for memories which, unimportant in themselves, are nevertheless indispensable as a bridge, in the sense that the association between two important memories can only be made through them.

The length of time during which a memory remains in the narrow defile in front of the patient's consciousness is, as has already been explained, in direct proportion to its importance. A picture which refuses to disappear is one which still calls for consideration, a thought which cannot be dismissed is one that needs to be pursued further. Moreover, a recollection never returns a second time once it has been dealt with; an image that has been 'talked away' is not seen again. If nevertheless this does happen we can confidently assume that the second time the image will be accompanied by a new set of thoughts, or the idea will have new implications. In other words, they have not been completely dealt with. Again, it frequently happens that an image or thought will re-appear in different degrees of intensity, first as a hint and later with complete clarity. This, however, does not contradict what I have just asserted.

Among the tasks presented by analysis is that of getting rid of symptoms which are capable of increasing in intensity or of returning: pains, symptoms (such as vomiting) which are due to stimuli, sensations or contractures. While we are working at one of these symptoms we come across the interesting and not undesired phenomenon of 'joining in the conversation'. The problematical symptom re-appears, or appears with greater intensity, as soon as we reach the region of the pathogenic organization which contains the symptom's aetiology, and thenceforward it accompanies the work with characteristic oscillations which are instructive to the physician. The intensity of the symptom (let us take for instance a desire to vomit) increases the deeper we penetrate into one of the relevant pathogenic memories; it reaches its climax shortly before the patient gives utterance to that memory; and when he has finished doing so it suddenly diminishes or even vanishes completely for a time. If, owing to resistance, the patient delays his telling for a long time, the tension of the sensation - of the desire to vomit - becomes unbearable, and if we cannot force him to speak he actually begins to vomit. In this way we obtain a plastic impression of the fact that 'vomiting' takes the place of a psychical act (in this instance, the act of utterance), exactly as the conversion theory of hysteria maintains.

This oscillation in intensity on the part of the hysterical symptom is then repeated every time we approach a fresh memory which is pathogenic in respect of it. The symptom, we might say, is on the agenda all the time. If we are obliged temporarily to drop the thread to which this symptom is attached, the symptom, too, retires into obscurity, to emerge once more at a later period of the analysis. This performance goes on until the working-over of the pathogenic material disposes of the symptom once and for all.

In all this, strictly speaking, the hysterical symptom is not behaving in any way differently from the memory-picture or the reproduced thought which we conjure up under the pressure of our hand. In both cases we find the same obsessively obstinate recurrence in the patient's memory, which has to be disposed of. The difference lies only in the apparently spontaneous emergence of the hysterical symptoms, while, as we very well remember, we ourselves provoked the scenes and ideas. In fact, however, there is an uninterrupted series, extending from the unmodified *mnemonic residues* of affective experiences and acts of thought to the hysterical symptoms, which are the *mnemonic symbols* of those experiences and thoughts.

The phenomenon of hysterical symptoms joining in the conversation during the analysis involves a practical drawback, to which we ought to be able to reconcile the patient. It is quite impossible to effect an analysis of a symptom at a single stretch or to distribute the intervals in our work so that they fit in precisely with pauses in the process of dealing with the symptom. On the contrary, interruptions which are imperatively prescribed by incidental circumstances in the treatment, such as the lateness of the hour, often occur at the most inconvenient points, just as one may be approaching a decision or just as a new topic emerges. Every newspaper reader suffers from the same drawback in reading the daily instalment of his serial story, when, immediately after the heroine's decisive speech or after the shot has rung out, he comes upon the words: 'To be continued.' In our own case the topic that has been raised but not dealt with, the symptom that has become temporarily intensified and has not yet been explained, persists in the patient's mind and may perhaps be more troublesome to him than it has otherwise been. He will simply have to make the best of this; there is no other way of arranging things. There are patients who, in the course of an analysis, simply cannot get free of a topic that has once been raised and who are obsessed by it in the interval between two treatments; since by themselves they cannot take any steps towards getting rid of it, they suffer more, to begin with, than they did before the treatment. But even such patients learn in the end to wait for the doctor and to shift all the interest that they feel in getting rid of the pathogenic material on to the hours of treatment, after which they begin to feel freer in the intervals.

The general condition of patients during an analysis of this kind also deserves notice. For a time it is uninfluenced by the treatment and continues to be an expression of the factors that were operative earlier. But after this there comes a moment when the treatment takes hold of the patient; it grips his interest, and thenceforward his general condition becomes more and more dependent on the state of the work. Every time something new is elucidated or an important stage in the process of the analysis is reached, the patient, too, feels relieved and enjoys a foretaste, as it were, of his approaching liberation. Every time the work halts and confusion threatens, the psychical burden by which he is oppressed increases; his feeling of unhappiness and his incapacity for work grow more intense. But neither of these things happens for more than a short time. For the analysis proceeds, disdaining to boast because the patient feels well for the time being and going on its way regardless of his periods of gloom. We feel glad, in general, when we have replaced the spontaneous oscillations in his condition by oscillations which we ourselves have provoked and which we understand, just as we are glad when we see the spontaneous succession of symptoms replaced by an order of the day which corresponds to the state of the analysis.

To begin with, the work becomes more obscure and difficult, as a rule, the deeper we penetrate into the stratified psychical structure which I have described above. But once we have worked our way as far as the nucleus, light dawns and we need not fear that the patient's general condition will be subject to any severe periods of gloom. But the reward of our labours, the cessation of the symptoms, can only be expected when we have accomplished the complete analysis of every individual symptom; and indeed, if the individual symptoms are interconnected at numerous nodal points, we shall not even be encouraged during the work by partial successes. Thanks to the abundant causal connections, every pathogenic idea which has not yet been got rid of operates as a motive for the whole of the products of the neurosis, and it is only with the last word of the analysis that the whole clinical picture vanishes, just as happens with memories that are reproduced individually.

If a pathogenic memory or a pathogenic connection which had formerly been withdrawn from the ego-consciousness is uncovered by the work of the analysis and introduced into the ego, we find that the psychological personality which is thus enriched has various ways of expressing itself with regard to what it has acquired. It happens particularly often that, after we have laboriously forced some piece of knowledge on a patient, he will declare: 'I've always known that, I could have told you that before.' Those with some degree of insight recognize afterwards that this is a piece of self-deception and blame themselves for being ungrateful. Apart from this, the attitude adopted by the ego to its new acquisition depends in general on the stratum of analysis from which that acquisition originates. Things that belong to the external strata are recognized without difficulty; they had, indeed, always remained in the ego's possession, and the only novelty to the ego is their connection with the deeper strata of pathological material. Things that are brought to light from these deeper strata are also recognized and acknowledged, but often only after considerable hesitations and doubts. Visual memory-images are of course more difficult to disavow than the memory-traces of mere trains of thought. Not at all infrequently the patient begins by saying: 'It's possible that I thought this, but I can't remember having done so.' And it is not until he has been familiar with the hypothesis for some time that he comes to recognize it as well; he remembers - and confirms the fact, too, by subsidiary links - that he really did once have the thought. I make it a rule, however, during the analysis to keep my estimate of the reminiscence that comes up independent of the patient's acknowledgement of it. I shall never be tired of repeating that we are bound to accept whatever our procedure brings to light. If there is anything in it that is not genuine or correct, the context will later on tell us to reject it. But I may say in passing that I have scarcely ever had occasion to disavow subsequently a reminiscence that has been provisionally accepted. Whatever has emerged has, in spite of the most deceptive appearance of being a glaring contradiction, nevertheless turned out to be correct.

The ideas which are derived from the greatest depth and which form the nucleus of the pathogenic organization are also those which are acknowledged as memories by the patient with greatest difficulty. Even when everything is finished and the patients have been overborne by the force of logic and have been convinced by the therapeutic effect accompanying the emergence of precisely these ideas - when, I say, the patients themselves accept the fact that they thought this or that, they often add: 'But I can't *remember* having thought it.' It is easy to come to terms with them by telling them that the thoughts were *unconscious*. But how is this state of affairs to be fitted into our own psychological views? Are we to disregard this withholding of recognition on the part of patients, when, now that the work is finished, there is no longer any motive for their doing so? Or are we to suppose that we are really dealing with thoughts which never came about, which merely had a *possibility* of existing, so that the treatment would lie in the accomplishment of a psychical act which did not take place at the time? It is clearly impossible to say anything about this - that is, about the state which the pathogenic material was in before the analysis - until we have arrived at a thorough clarification of our basic psychological views, especially on the nature of consciousness. It remains, I think, a fact deserving serious consideration that in our analyses we can follow a train of thought from the conscious into the unconscious (i.e. into something that is absolutely not recognized as a memory), that we can trace it from there for some distance through consciousness once more and that we can see it terminate in the unconscious again, without this alternation of 'psychical illumination' making any change in the train of thought itself, in its logical consistency and in the interconnection between its various parts. Once this train of thought was before me as a whole I should not be able to guess which part of it was recognized by the patient as a memory and which was not. I only, as it were, see the peaks of the train of thought dipping down into the unconscious - the reverse of what has been asserted of our normal psychical processes.

I have finally to discuss yet another topic, which plays an undesirably large part in the carrying out of cathartic analyses such as these. I have already admitted the possibility of the pressure technique failing, of its not eliciting any reminiscence in spite of every assurance and insistence. If this happens, I said, there are two possibilities: either, at the point at which we are investigating, there is really nothing more to be found - and this we can recognize from the complete calmness of the patient's facial expression; or we have come up against a resistance which can only be overcome later, we are faced by a new stratum into which we cannot yet penetrate - and this, once more, we can infer from the patient's facial expression, which is tense and gives evidence of mental effort. But there is yet a third possibility which bears witness equally to an obstacle, but an external obstacle, and not one inherent in the material. This happens when the patient's relation to the physician is disturbed, and it is the worst obstacle that we can come across. We can, however, reckon on meeting it in every comparatively serious analysis.

I have already indicated the important part played by the figure of the physician in creating motives to defeat the psychical force of resistance. In not a few cases, especially with women and where it is a question of elucidating erotic trains of thought, the patient's co-operation becomes a personal sacrifice, which must be compensated by some substitute for love. The trouble taken by the physician and his friendliness have to suffice for such a substitute. If, now, this relation of the patient to the physician is disturbed, her co-operativeness fails, too; when the physician tries to investigate the next pathological idea, the patient is held up by an intervening consciousness of the complaints against the physician that have been accumulating in her. In my experience this obstacle arises in three principal cases.

(1) If there is a personal estrangement - if, for instance, the patient feels she has been neglected, has been too little appreciated or has been insulted, or if she has heard unfavourable comments on the physician or the method of treatment. This is the least serious case. The obstacle can easily be overcome by discussion and explanation, even though the sensitiveness and suspiciousness of hysterical patients may occasionally attain surprising dimensions.

(2) If the patient is seized by a dread of becoming too much accustomed to the physician personally, of losing her independence in relation to him, and even of perhaps becoming sexually dependent on him. This is a more important case, because its determinants are less individual. The cause of this obstacle lies in the special solicitude inherent in the treatment. The patient then has a new motive for resistance, which is manifested not only in relation to some particular reminiscence but at every attempt at treatment. It is quite common for the patient to complain of a headache when we start on the pressure procedure; for her new motive for resistance remains as a rule unconscious and is expressed by the production of a new hysterical symptom. The headache indicates her dislike of allowing herself to be influenced.

(3) If the patient is frightened at finding that she is transferring on to the figure of the physician the distressing ideas which arise from the content of the analysis. This is a frequent, and indeed in some analyses a regular, occurrence. Transference on to the physician takes place through a *false connection*. I must give an example of this. In one of my patients the origin of a particular hysterical symptom lay in a wish, which she had had many years earlier and had at once relegated to the unconscious, that the man she was talking to at the time might boldly take the initiative and give her a kiss. On one occasion, at the end of a session, a similar wish came up in her about me. She was horrified at it, spent a sleepless night, and at the next session, though she did not refuse to be treated, was quite useless for work. After I had discovered the obstacle and removed it, the work proceeded further; and lo and behold: the wish that had so much frightened the patient made its appearance as the next of her pathogenic recollections and the one which was demanded by the immediate logical context. What had happened therefore was this. The content of the wish had appeared first of all in the patient's consciousness without any memories of the surrounding circumstances which would have assigned it to a past time. The wish which was present was then, owing to the compulsion to associate which was dominant in her consciousness, linked to my person, with which the patient was legitimately concerned; and as the result of this *mésalliance* - which I describe as a 'false connection' - the same affect was provoked which had forced the patient long before to repudiate this forbidden wish. Since I have discovered this, I have been able, whenever I have been similarly involved personally, to presume that a transference and a false connection have once more taken place. Strangely enough, the patient is deceived afresh every time this is repeated.

It is impossible to carry any analysis to a conclusion unless we know how to meet the resistance arising in these three ways. But we can find a way of doing so if we make up our minds that this new symptom that has been produced on the old model must be treated in the same way as the old symptoms. Our first task is to make the 'obstacle' conscious to the patient. In one of my patients, for instance, the pressure procedure suddenly failed. I had reason to suppose that there was an unconscious idea of the kind mentioned under (2) above, and I dealt with it at the first attempt by taking her by surprise. I told her that some obstacle must have arisen to continuing the treatment, but that the pressure procedure had at least the power to show her what this obstacle was; I pressed on her head, and she said in astonishment: 'I see you sitting on the chair here; but that's nonsense. What can it mean?' I was then able to enlighten her. With another patient the 'obstacle' used not to appear directly as a result of my pressure, but I was always able to discover it if I took the patient back to the moment at which it had originated. The pressure procedure never failed to bring this moment back for us. When the obstacle had been discovered and demonstrated the first difficulty was cleared out of the way. But a greater one remained. It lay in inducing the patient to produce information where apparently personal relations were concerned and where the third person coincided with the figure of the physician.

To begin with I was greatly annoyed at this increase in my psychological work, till I came to see that the whole process followed a law; and I then noticed, too, that transference of this kind brought about no great addition to what I had to do. For the patient the work remained the same: she had to overcome the distressing affect aroused by having been able to entertain such a wish even for a moment; and it seemed to make no difference to the success of the treatment whether she made this psychical repudiation the theme of her work in the historical instance or in the recent one connected with me. The patients, too, gradually learnt to realize that in these transferences on to the figure of the physician it was a question of a compulsion and an illusion which melted away with the conclusion of the analysis. I believe, however, that if I had neglected to make the nature of the 'obstacle' clear to them I should simply have given them a new hysterical symptom - though, it is true, a milder one - in exchange for another which had been generated spontaneously.

I have now given enough indications, I think, of the way in which these analyses have been carried out and of the observations that I have made in the course of them. What I have said may perhaps make some things seem more complicated than they are. Many problems answer themselves when we find ourselves engaged in such work. I did not enumerate the difficulties of the work in order to create an impression that, in view of the demands a cathartic analysis makes on physician and patient alike, it is only worth while undertaking one in the rarest cases. I allow my medical activities to be governed by the contrary assumption, though I cannot, it is true, lay down the most definite indications for the application of the therapeutic method described in these pages without entering into an examination of the more important and comprehensive topic of the treatment of the neuroses in general. I have often in my own mind compared cathartic psychotherapy with surgical intervention. I have described my treatments as psychotherapeutic operations; and I have brought out their analogy with the opening up of a cavity filled with pus, the scraping out of a carious region, etc. An analogy of this kind finds its justification not so much in the removal of what is pathological as in the establishment of conditions that are more likely to lead the course of the process in the direction of recovery.

When I have promised my patients help or improvement by means of a cathartic treatment I have often been faced by this objection: 'Why, you tell me yourself that my illness is probably connected with my circumstances and the events of my life. You cannot alter these in any way. How do you propose to help me, then?' And I have been able to make this reply: 'No doubt fate would find it easier than I do to relieve you of your illness. But you will be able to convince yourself that much will be gained if we succeed in transforming your hysterical misery into common unhappiness. With a mental life that has been restored to health you will be better armed against that unhappiness.'

PREFACE TO FREUD'S SHORTER WRITINGS 1893-1906
(1906)

Intentionally left blank

PREFACE TO FREUD'S COLLECTION OF SHORTER WRITINGS ON THE THEORY OF THE NEUROSES FROM THE YEARS 1893-1906

In response to many wishes that have reached me, I have decided to lay before my colleagues in collected form the minor works on the neuroses which I have published since 1893. They consist of fourteen short papers, mostly in the nature of preliminary communications, which have appeared in scientific proceedings or medical periodicals - three of them in French. The two last (XIII and XIV), which give a very succinct account of my present position as regards both the aetiology and the treatment of the neuroses, are taken from L. Löwefeld's well-known volumes, *Die psychischen Zwangsercheinungen*, 1904, and the fourth edition of *Sexualleben und Nervenleiden*, 1906, having been written by me at the request of their author, who is an acquaintance of mine.

The present collection serves as an introduction and supplement to my larger publications dealing with the same topics - *Studies on Hysteria* (with Dr. J. Breuer), 1895; *The Interpretation of Dreams*, 1900; *The Psychopathology of Everyday Life*, 1901 and 1904; *Jokes and their Relation to the Unconscious*, 1905; *Three Essays on the Theory of Sexuality*, 1905; *Fragment of an Analysis of a Case of Hysteria*, 1905. The fact that I have put my Obituary of J.-M. Charcot at the head of this collection of my short papers should be regarded not only as the repayment of a debt of gratitude, but also as an indication of the point at which my own work branches off from the master's.

No one who is familiar with the course of development of human knowledge will be surprised to learn that I have in the meantime gone beyond some of the opinions which are expressed here, and have seen my way to modifying others. Nevertheless, I have been able to retain the greater part of them unaltered and in fact have no need to withdraw anything as wholly erroneous or completely worthless.

CHARCOT
(1893)

Intentionally left blank

CHARCOT

On the 16th of August of this year, J.M. Charcot died suddenly, without pain or illness, after a life of happiness and fame. In him, all too soon, the young science of neurology has lost its greatest leader, neurologists of every country have lost their master teacher and France has lost one of her foremost men. He was only sixty-eight years old; his physical strength and mental vigour, together with the hopes he so frankly expressed, seemed to promise him the long life which has been granted to not a few mental workers of this century. The nine imposing volumes of his *Oeuvres complètes*, in which his pupils had collected his contributions to medicine and neuropathology, his *Leçons du mardi*, the yearly reports of his clinic at the Salpêtrière, and other works besides - all these publications will remain precious to science and to his pupils; but they cannot take the place of the man, who had still much more to give and to teach and whose person or whose writings no one has yet approached without learning something from them.

He took an honest, human delight in his own great success and used to enjoy talking of his beginnings and the road he had travelled. His scientific curiosity, he said, had been aroused early, when he was still a young *interne*, by the mass of material presented by the facts of neuropathology, material which was not in the least understood at the time. In those days, whenever he went the rounds with his senior in one of the departments of the Salpêtrière (the institution for the care of women) amid all the wilderness of paralyses, spasms and convulsions for which forty years ago there was neither name nor understanding, he would say: '*Faudrait y retourner et y rester*', and he kept his word. When he became *médecin des hôpitaux*, he at once took steps to enter the Salpêtrière in one of the departments for nervous patients. Having got there, he stayed where he was instead of doing what French senior physicians are entitled to do - transferring in regular succession from one department to another and from hospital to hospital, and at the same time changing their speciality as well.

Thus his first impression and the resolution it led him to were decisive for the whole of his further development. His having a great number of chronic nervous patients at his disposal enabled him to make use of his own special gifts. He was not a reflective man, not a thinker: he had the nature of an artist - he was, as he himself said, a '*visuel*', a man who sees. Here is what he himself told us about his method of working. He used to look again and again at the things he did not understand, to deepen his impression of them day by day, till suddenly an understanding of them dawned on him. In his mind's eye the apparent chaos presented by the continual repetition of the same symptoms then gave way to order: the new nosological pictures emerged, characterized by the constant combination of certain groups of symptoms. The complete and extreme cases, the 'types', could be brought into prominence with the help of a certain sort of schematic planning, and, with these types as a point of departure, the eye could travel over the long series of ill-defined cases - the '*formes frustes*' - which, branching off from one or other characteristic feature of the type, melt away into indistinctness. He called this kind of intellectual work, in which he had no equal, 'practising nosography', and he took pride in it. He might be heard to say that the greatest satisfaction a man could have was to see something new - that is, to recognize it as new; and he remarked again and again on the difficulty and value of this kind of 'seeing'. He would ask why it was that in medicine people only see what they have already learned to see. He would say that it was wonderful how one was suddenly able to see new things - new states of illness - which must probably be as old as the human race; and that he had to confess to himself that he now saw a number of things which he had overlooked for thirty years in his hospital wards. No physician needs to be told what a wealth of forms were acquired by neuropathology through him, and what increased precision and sureness of diagnosis were made possible by his observations. But the pupil who spent many hours with him going round the wards of the Salpêtrière - that museum of clinical facts, the names and peculiar characteristics of which were for the most part derived from him would be reminded of Cuvier, whose statue, standing in front of the Jardin des Plantes, shows that great comprehender and describer of the animal world surrounded by a multitude of animal forms; or else he would recall the myth of Adam, who, when God brought the creatures of Paradise before him to be distinguished and named, may have experienced to the fullest degree that intellectual enjoyment which Charcot praised so highly.

Charcot, indeed, never tired of defending the rights of purely clinical work, which consists in seeing and ordering things, against the encroachments of theoretical medicine. On one occasion there was a small group of us, all students from abroad, who, brought up on German academic physiology, were trying his patience with our doubts about his clinical innovations. 'But that can't be true,' one of us objected, 'it contradicts the Young-Helmholtz theory.' He did not reply 'So much the worse for the theory, clinical facts come first' or words to that effect; but he did say something which made a great impression on us: '*La theorie, c'est bon, mais ca n'empeche pas d'exister*'.

For a whole number of years Charcot occupied the Chair of Pathological Anatomy in Paris, and he carried on his neuropathological studies and lectures, which quickly made him famous abroad as well as in France, on a voluntary basis and as a secondary occupation. It was a piece of good fortune for neuropathology that the same man could undertake the discharge of two functions: on the one hand he created the nosological picture through clinical observation, and on the other he demonstrated that the same anatomical changes underlay the disease whether it appeared as a type or as a *forme fruste*. It is very generally recognized how successful this anatomical clinical method of Charcot's was in the field of organic nervous diseases - in tabes, multiple sclerosis, amyotrophic lateral sclerosis, and so on. Years of patient waiting were often necessary before the presence of organic change could be proved in those chronic illnesses which are not directly fatal; and only in a hospital for incurables like the Salpêtrière was it possible to keep the patients under observation for such long periods of time. Charcot made his first demonstration of this kind before he had charge of a department. While he was still a student he happened to engage a maid-servant who suffered from a peculiar tremor and could not find a situation on account of her clumsiness. Charcot recognized her condition as a *paralysie choréiforme*, a disease which had already been described by Duchenne, but whose basis was unknown. Charcot kept this interesting servant, although in the course of the years she cost him a small fortune in dishes and plates. When at last she died he was able to demonstrate from her case that *paralysie choréiforme* was the clinical expression of multiple cerebro-spinal sclerosis.

Pathological anatomy has to serve neuropathology in two ways. Besides demonstrating the presence of a morbid change, it must establish the localization of that change; and we all know that during the last two decades the second part of this task has aroused the greater interest of the two and has been more actively pursued. Charcot played a most distinguished part in this work, too, although the pioneer discoveries were not made by him. To begin with he followed in the footsteps of our fellow-countryman, Türck, who is said to have lived and carried on his researches in comparative isolation among us. When the two great innovations came - the Hitzig-Fritsch stimulation experiments and Flechsig's findings on the development of the spinal cord - which ushered in a new epoch in our knowledge of the 'localization of nervous diseases', Charcot's lectures on localization played the largest and best part towards bringing the new theories into touch with the clinical work and making them fruitful for it. As regards in especial the relationship of the somatic muscular apparatus to the motor area of the human cerebrum, I may remind the reader of the long time during which the more exact nature and topography of this relationship was in question. (Was there a common representation of both extremities in the same areas? or was there a representation of the upper extremity in the anterior central convolution and if the lower extremity in the posterior one - that is, a vertical disposition?) At last, continued clinical observations and experiments in stimulation and extirpation on living subjects during surgical operations decided the question in favour of the view of Charcot and Pitres that the middle third of the central convolutions mainly serves the representation of the arm, while the upper third and the mesial portion serve that of the leg - that is to say, that in the motor area the disposition is a horizontal one.

An enumeration of Charcot's separate contributions would not enable us to establish his significance for neuropathology. For during the last two decades there have not been many themes of any importance in whose formulation and discussion the school of the Salpêtrière has not had an outstanding share; and the 'school of the Salpêtrière' was, of course, Charcot himself, who, with the wealth of his experience, the transparent clarity of his diction and the plasticity of his descriptions, could easily be recognized in every publication of the school. Among the circle of young men whom he thus gathered round him and made into participants in his researches, a few eventually rose to a consciousness of their own individuality and made a brilliant name for themselves. Now and then, even, it happened that one of them would come forward with an assertion which seemed to the master to be more clever than correct; and this he would argue against with plenty of sarcasm in his conversation and lectures, but without doing any damage to his affectionate relationship with his pupil. And in fact Charcot leaves behind him a host of pupils whose intellectual quality and whose achievements up to now are a guarantee that the study and practice of neuropathology in Paris will not so quickly slip down from the height to which Charcot has brought them.

In Vienna we have repeatedly had occasion to realize that the intellectual significance of an academic teacher is not necessarily combined with a direct personal influence on younger men which leads to the creation of a large and important school. If Charcot was so much more fortunate in this respect we must put it down to the personal qualities of the man - to the magic that emanated from his looks and from his voice, to the kindly openness which characterized his manner as soon as his relations with someone had overcome the stage of initial strangeness, to the willingness with which he put everything at the disposal of his pupils, and to his life-long loyalty to them. The hours he spent in his wards were hours of companionship and of an exchange of ideas with the whole of his medical staff. He never shut himself away from them there. The youngest newly-qualified physician walking the wards had a chance of seeing him at his work and might interrupt him at it; and the same freedom was enjoyed by students from abroad, who, in later years, were never lacking at his rounds. And, lastly, on the evenings when Madame Charcot was at home to a distinguished company, assisted by a highly-gifted daughter who was growing up in the likeness of her father, the pupils and medical assistants who were always present met the guests as part of the family.

In 1882 or 1883, the circumstances of Charcot's life and work took on their final form. People had come to realize that the activities of this man were a part of the assets of the nation's '*gloire*', which, after the unfortunate war of 1870-1, was all the more jealously guarded. The government, at the head of which was Charcot's old friend, Gambetta, created a Chair of Neuropathology for him in the Faculty of Medicine (so that he could give up the Chair of Pathological Anatomy) and also a clinic, with auxiliary scientific departments, at the Salpêtrière. '*Le service de M. Charcot*' now included, in addition to the old wards for chronic female patients, several clinical rooms where male patients, too, were received, a huge out-patient department - the '*consultation externe*' -, a histological laboratory, a museum, an electro-therapeutic department, an eye and ear department and a special photographic studio. All these things were so many means of keeping former assistants and pupils permanently at the clinic in secure posts. The two-storeyed, weathered-looking buildings and the courtyards which they enclosed reminded the stranger vividly of our *Allgemeines Krankenhaus*; but no doubt the resemblance did not go far enough. 'It may not be beautiful here, perhaps,' Charcot would say when he showed a visitor his domain, 'but there is room for everything you want to do.'

Charcot was in the very prime of life when this abundance of facilities for teaching and research were placed at his disposal. He was a tireless worker, and always, I believe, the busiest in the whole institute. His private consultations, to which patients flocked 'from Samarkand and the Antilles', could not keep him from his teaching activities or his researches. There is no doubt that this throng of people did not turn to him solely because he was a famous discoverer but quite as much because he was a great physician and friend of man, who could always find an answer to a problem and who, when the present state of science did not allow him to *know*, was able to make a good guess. He has often been blamed for his therapeutic method which, with its multiplicity of prescriptions, could not but offend a rationalistic conscience. But he was simply continuing the procedures which were customary at that time and place, without deceiving himself much about their efficacy. He was, however, not pessimistic in his therapeutic expectations, and repeatedly showed readiness to try new methods of treatment in his clinic: their short-lived success was to find its explanation elsewhere.

As a teacher, Charcot was positively fascinating. Each of his lectures was a little work of art in construction and composition; it was perfect in form and made such an impression that for the rest of the day one could not get the sound of what he had said out of one's ears or the thought of what he had demonstrated out of one's mind. He seldom demonstrated a single patient, but mostly a series of similar or contrasting cases which he compared with one another. In the hall in which he gave his lectures there hung a picture which showed 'citizen' Pinel having the chains taken off the poor madmen in the Salpêtrière. The Salpêtrière, which had witnessed so many horrors during the Revolution, had also been the scene of this most humane of all revolutions. At such lectures Maître Charcot himself made a curious impression. He, who at other times bubbled over with vivacity and cheerfulness and who always had a joke on his lips, now looked serious and solemn under his little velvet cap; indeed, he even seemed to have grown older. His voice sounded subdued. We could almost understand how ill-disposed strangers could reproach the whole lecture with being theatrical. Those who spoke like this were doubtless accustomed to the formlessness of German clinical lectures, or else forgot that Charcot gave only *one* lecture in the week and could therefore prepare it carefully.

In this formal lecture, in which everything was prepared and everything had to have its place, Charcot was no doubt following a deeply-rooted tradition; but he also felt the need to give his audience a less elaborated picture of his activities. This purpose was served by his out-patient clinic of which he took personal charge in what were known as his '*Leçons du mardi*'. There he took up cases which were completely unknown to him; he exposed himself to all the chances of an examination, all the errors of a first investigation; he would put aside his authority on occasion and admit - in one case that he could arrive at no diagnosis and in another that he had been deceived by appearances; and he never appeared greater to his audience than when, by giving the most detailed account of his processes of thought and by showing the greatest frankness about his doubts and hesitations, he had thus sought to narrow the gulf between teacher and pupil. The publication of these improvised lectures, given in the year 1887 and 1888, at first in French and now in German as well, has also immeasurably widened the circle of his admirers; and never before has a work on neuropathology had such a success with the medical public as this.

At about the time at which the clinic was established and at which he gave up the Chair of Pathological Anatomy, a change occurred in the direction of Charcot's scientific pursuits, and to this we owe the finest of his work. He now pronounced that the theory of organic nervous illnesses was for the time being fairly complete, and he began to turn his attention almost exclusively to hysteria, which thus all at once became the focus of general interest. This, the most enigmatic of all nervous diseases, for the evaluation of which medicine had not yet found a serviceable angle of approach, had just then fallen into thorough discredit; and this discredit extended not only to the patients but to the physicians who concerned themselves with the neurosis. It was held that in hysteria anything was possible, and no credence was given to a hysteric about anything. The first thing that Charcot's work did was to restore its dignity to the topic. Little by little, people gave up the scornful smile with which the patient could at that time feel certain of being met. She was no longer necessarily a malingerer, for Charcot had thrown the whole weight of his authority on the side of the genuineness and objectivity of hysterical phenomena. Charcot had repeated on a small scale the act of liberation in memory of which Pinel's portrait hung in the lecture hall of the Salpêtrière. Once the blind fear of being made a fool of by the unfortunate patient had been given up - a fear which till then had stood in the way of a serious study of the neurosis - the question could arise as to what method of approach would lead most quickly to a solution of the problem. A quite unbiased observer might have arrived at this conclusion: if I find someone in a state which bears all the signs of a painful affect - weeping, screaming and raging - the conclusion seems probable that a mental process is going on in him of which those physical phenomena are the appropriate expression. A healthy person, if he were asked, would be in a position to say what impression it was that was tormenting him; but the hysteric would answer that he did not know. The problem would at once arise of how it is that a hysterical patient is overcome by an affect about whose cause he asserts that he knows nothing. If we keep to our conclusion that a corresponding psychical process *must* be present, and if nevertheless we believe the patient when he denies it; if we bring together the many indications that the patient is behaving as though he *does* know about it; and if we enter into the history of the patient's life and find some occasion, some trauma, which would appropriately evoke precisely those expressions of feeling - then everything points to one solution: the patient is in a special state of mind in which all his impressions or his recollections of them are no longer held together by an associative chain, a state of mind in which it is possible for a recollection to express its affect by means of somatic phenomena without the group of the other mental processes, the ego, knowing about it or being able to intervene to prevent it. If we had called to mind the familiar psychological difference between sleep and waking, the strangeness of our hypothesis might have seemed less. No one should object that the theory of a splitting of consciousness as a solution to the riddle of hysteria is much too remote to impress an unbiased and untrained observer. For, by pronouncing possession by a demon to be the cause of hysterical phenomena, the Middle Ages in fact chose this solution; it would only have been a matter of exchanging the religious terminology of that dark and superstitious age for the scientific language of to-day.

Charcot, however, did not follow this path towards an explanation of hysteria, although he drew copiously upon the surviving reports of witch trials and of possession, in order to show that the manifestations of the neurosis were the same in those days as they are now. He treated hysteria as just another topic in neuropathology; he gave a complete description of its phenomena, demonstrated that these had their own laws and uniformities, and showed how to recognize the symptoms which enable a diagnosis of hysteria to be made. The most painstaking investigations, initiated by himself and his pupils, extended over hysterical disturbances of sensibility in the skin and deeper tissues, over the behaviour of the sense organs, and over the peculiarities of hysterical contractures and paralyses, and of trophic disturbances and changes in metabolism. The many different forms of hysterical attack were described, and a schematic plan was drawn up by depicting the typical configuration of the major hysterical attack as occurring in four stages, which made it possible to trace the commonly observed 'minor' attacks back to this same typical configuration. The localization and frequency of occurrence of the so-called 'hysterogenic zones' and their relationship to the attacks were also studied, and so on. Once all this information about the manifestations of hysteria had been arrived at, a number of surprising discoveries were made. Hysteria in males, and especially in men of the working class was found far more often than had been expected; it was convincingly shown that certain conditions which had been put down to alcoholic intoxication or lead-poisoning were of a hysterical nature; it was possible to subsume under hysteria a whole number of affections which had hitherto not been understood and which had remained unclassified; and where the neurosis had become joined with other disorders to form complex pictures, it was possible to separate out the part played by hysteria. Most far-reaching of all were the investigations into nervous illnesses which followed upon severe traumas - the 'traumatic neuroses' - views about which are still under discussion and in connection with which Charcot has successfully put forward the arguments in favour of hysteria.

After the latest extensions of the concept of hysteria had so often led to a rejection of aetiological diagnosis, it became necessary to enter into the aetiology of hysteria itself. Charcot put forward a simple formula for this: heredity was to be regarded as the sole cause. Accordingly, hysteria was a form of degeneracy, a member of the '*famille névropathique*'. All other aetiological factors played the part of incidental causes, of '*agents provocateurs*'.

The construction of this great edifice was naturally not achieved without violent opposition. But it was the sterile opposition of an old generation who did not want to have their views changed. The younger among the neuropathologists, including those in Germany, accepted Charcot's teaching to a greater or lesser degree. Charcot himself was completely certain that his theories about hysteria would triumph. When it was objected that the four stages of hysteria, hysteria in men, and so on, were not observable outside France, he pointed out how long he himself had overlooked these things, and he said once more that hysteria was the same in all places and at every time. He was very sensitive about the accusation that the French were a far more neurotic nation than any other and that hysteria was a kind of national bad habit; and he was much pleased when a paper 'On a Case of Reflex Epilepsy', which dealt with a Prussian Grenadier, enabled him to make a long range diagnosis of hysteria.

At one point in his work Charcot rose to a level higher even than that of his usual treatment of hysteria. The step he took assured him for all time, too, the fame of having been the first to explain hysteria. While he was engaged in the study of hysterical paralyses arising after traumas, he had the idea of artificially reproducing those paralyses, which he had earlier differentiated with care from organic ones. For this purpose he made use of hysterical patients whom he put into a state of somnambulism by hypnotizing them. He succeeded in proving, by an unbroken chain of argument, that these paralyses were the result of ideas which had dominated the patient's brain at moments of a special disposition. In this way, the mechanism of a hysterical phenomenon was explained for the first time. This incomparably fine piece of clinical research was afterwards taken up by his own pupil, Pierre Janet, as well as by Breuer and others, who developed from it a theory of neurosis which coincided with the mediaeval view - when once they had replaced the 'demon' of clerical phantasy by a psychological formula.

Charcot's concern with hypnotic phenomena in hysterical patients led to very great advances in this important field of hitherto neglected and despised facts, for the weight of his name put an end once and for all to any doubt about the reality of hypnotic manifestations. But the exclusively nosographical approach adopted at the School of the Salpêtrière was not suitable for a purely psychological subject. The restriction of the study of hypnosis to hysterical patients, the differentiation between major and minor hypnotism, the hypothesis of three stages of 'major hypnosis', and their characterization by somatic phenomena - all this sank in the estimation of Charcot's contemporaries when Liébeault's pupil, Bernheim, set about constructing the theory of hypnotism on a more comprehensive psychological foundation and making suggestion the central point of hypnosis. It is only the opponents of hypnotism who, content to conceal their lack of personal experience behind an appeal to authority, still cling to Charcot's assertions and who like to take advantage of a pronouncement made by him in his last years, in which he denied to hypnosis any value as a therapeutic method.

Furthermore, the aetiological theories supported by Charcot in his doctrine of the '*famille névropathique*', which he made the basis of his whole concept of nervous disorders, will no doubt soon require sifting and emending. So greatly did Charcot over-estimate heredity as a causative agent that he left no room for the acquisition of nervous illness. To syphilis he merely allotted a modest place among the '*agents provocateurs*'; nor did he make a sufficiently sharp distinction between organic nervous affections and neuroses, either as regards their aetiology or in other respects. It is inevitable that the advance of our science, as it increases our knowledge, must at the same time lessen the value of a number of things that Charcot taught us; but neither changing times nor changing views can diminish the fame of the man whom - in France and elsewhere - we are mourning to-day.

ON THE PSYCHICAL MECHANISM OF HYSTERICAL PHENOMENA ¹

Gentlemen, - I am appearing before you to-day with the object of giving you a report on a work the first part of which has already been published in the *Zentralblatt für Neurologie* under the names of Josef Breuer and myself. As you may gather from the title of the work, it deals with the pathogenesis of hysterical symptoms and suggests that the immediate reasons for the development of hysterical symptoms are to be looked for in the sphere of psychical life.

But before I enter further into the contents of this joint work, I must explain the position it occupies and name the author and the discovery which, in substance at least, we have taken as our starting point, although our contribution has been developed quite independently.

As you know, Gentlemen, all the modern advances made in the understanding and knowledge of hysteria are derived from the work of Charcot. In the first half of the eighties, Charcot began to turn his attention to the 'major neurosis', as the French call hysteria. In a series of researches he has succeeded in proving the presence of regularity and law where the inadequate or half-hearted clinical observations of other people saw only malingering or a puzzling lack of conformity to rule. It may safely be said that everything new that has been learnt about hysteria in recent times goes back directly or indirectly to his suggestions. But among Charcot's numerous works, none, in my estimate, is of higher value than the one in which he taught us to understand the traumatic paralyses which appear in hysteria; and since it is precisely this work of which ours appears as a continuation, I hope you will allow me to lay this subject before you once again in some detail.

¹ A lecture delivered by Dr. Sigm. Freud at a meeting of the 'Wiener medizinischer Club' on January 11, 1893. Special shorthand report by the *Wiener medizinische Presse*, revised by the lecturer.

We will take the case of a person who is subjected to a trauma without having been ill previously and perhaps without ever having any hereditary taint. The trauma must fulfil certain conditions. It must be severe - that is, it must be of a kind involving the idea of mortal danger, of a threat to life. But it must not be severe in the sense of bringing psychical activity to an end. Otherwise it will not produce the result we expect from it. Thus, for instance, it must not involve concussion of the brain or any really serious injury. Moreover, the trauma must have a special relation to some part of the body. Let us suppose that a heavy billet of wood falls on a workman's shoulder. The blow knocks him down, but he soon realizes that nothing has happened and goes home with a slight contusion. After a few weeks, or after some months, he wakes up one morning and notices that the arm that was subjected to the trauma is hanging down limp and paralysed, though in the interval, in what might be called the incubation period, he has made perfectly good use of it. If the case is a typical one, it may happen that peculiar attacks set in - that, after an aura, the subject suddenly collapses, raves, and becomes delirious; and, if he speaks in his delirium, what he says may show that the scene of his accident is being repeated in him, embellished, perhaps, with various imaginary pictures. What has been happening here? How is this phenomenon to be explained?

Charcot explains the process by reproducing it, by inducing the paralysis in a patient artificially. In order to bring this about, he needs a patient who is already in a hysterical state; he further requires the condition of hypnosis and the method of suggestion. He puts a patient of this kind into deep hypnosis and gives him a light blow on the arm. The arm drops; it is paralysed and shows precisely the same symptoms as occur in spontaneous traumatic paralysis. The blow may also be replaced by a direct verbal suggestion: 'Look! your arm is paralysed!' In this case too the paralysis exhibits the same characteristics.

Let us try to compare the two cases: on the one hand a trauma, on the other a traumatic suggestion. The final result, the paralysis, is exactly the same in both cases. If the trauma in the one case can be replaced in the other case by a verbal suggestion, it is plausible to suppose that an idea of this kind was responsible for the development of the paralysis in the case of the spontaneous traumatic paralysis as well. And in fact a number of patients report that at the moment of the trauma they actually had a feeling that their arm was smashed. If this were so, the trauma could really be completely equated with the verbal suggestion. But to complete the analogy a third factor is required. In order that the idea 'your arm is paralysed' should be able to provoke a paralysis in the patient, it was necessary for him to be in a state of hypnosis. But the workman was not in a state of hypnosis. Nevertheless, we may assume that he was in a special state of mind during the trauma; and Charcot is inclined to equate that affect with the artificially induced state of hypnosis. This being so, the traumatic spontaneous paralysis is completely explained and brought into line with the paralysis produced by suggestion; and the genesis of the symptom is unambiguously determined by the circumstances of the trauma.

Charcot has, moreover, repeated the same experiment in order to explain the contractures and pains which appear in traumatic hysteria; and in my opinion there is scarcely any point at which he has penetrated into the understanding of hysteria more deeply than here. But his analysis goes no further: we do not learn how other symptoms are generated, and above all we do not learn how hysterical symptoms come about in common, non-traumatic hysteria.

At about the same time, Gentlemen, at which Charcot was thus throwing light on hystero-traumatic paralyses, Dr. Breuer between 1880 and 1882, undertook the medical care of a young lady who - with a non-traumatic aetiology - fell ill of a severe and complicated hysteria (accompanied by paralyses, contractures, disturbances of speech and vision, and psychical peculiarities of every kind), while she was nursing her sick father. This case will retain an important place in the history of hysteria, since it was the first one in which a physician succeeded in elucidating all the symptoms of the hysterical state, in learning the origin of each symptom and at the same time in finding a means of causing that symptom to disappear. We may say that it was the first case of hysteria to be made intelligible. Dr. Breuer kept back the conclusions which followed from this case till he could be certain that it did not stand alone. After I returned, in 1886, from a course of study under Charcot, I began, with Breuer's constant co-operation, to make close observations on a fairly large number of hysterical patients and to examine them from this point of view; and I found that the behaviour of this first patient had in fact been typical and that the inferences which were justified by that case could be carried over to a considerable number of hysterical patients, if not to all.

Our material consisted of cases of common, that is of non-traumatic, hysteria. Our procedure was to take each separate symptom and enquire into the circumstances in which it had made its first appearance; and we endeavoured in this way to arrive at a clear idea of the precipitating cause that symptom. Now you must not suppose that this is a simple job. If you question patients along these lines, you will as a rule receive no answer at all to begin with. In a small group of cases the patients have their reasons for not saying what they know. But in a greater number of cases the patients have no notion of the context of their symptoms. The method by which something can be learnt is an arduous one. It is as follows. The patients must be put under hypnosis and then questioned as to the origin of some particular symptom - as to when it first appeared and what they remember in that connection. While they are in this state, the memory, which was not at their disposal in a waking state, returns. We have learnt in this manner that, to put it roughly, there is an affectively coloured experience behind most, if not all, phenomena of hysteria; and further, that this experience is of such a kind that it at once makes the symptom to which it relates intelligible and shows accordingly that the symptom, once again, is unambiguously determined. If you will allow me to equate this affectively coloured experience with the major traumatic experience underlying traumatic hysteria, I can at once formulate the first thesis at which we have arrived: '*There is a complete analogy between traumatic paralysis and common, non-traumatic hysteria.*' The only difference is that in the former a major trauma has been operative, whereas in the latter there is seldom a *single* major event to be signaled, but rather a *series* of affective impressions - a whole story of suffering. But there is nothing forced in equating such a story, which appears as the determining factor in hysterical patients, with the accident which occurs in traumatic hysteria. For no one doubts any longer to-day that even in the case of the major mechanical trauma in traumatic hysteria what produces the result is not the mechanical factor but the affect of fright, the *psychical* trauma. The first thing that follows from all this, then, is that the pattern of traumatic hysteria, as it was laid down by Charcot for hysterical paralyses, applies quite generally to all hysterical phenomena, or at least to the great majority of them. In every case what we have to deal with is the operation of psychical traumas, which unambiguously determine the nature of the symptoms that arise.

I will now give you a few instances of this. First, here is an example of the occurrence of contractures. Throughout the whole period of her illness, Breuer's patient, whom I have already mentioned, exhibited a contracture of the right arm. It emerged under hypnosis that at a time before she had fallen ill she was subjected to the following trauma. She was sitting half-dozing at the bedside of her sick father; her right arm was hanging over the back of her chair and went to sleep. At this moment she had a terrifying hallucination; she tried to fend it off with her arm but was unable to do so. This gave her a violent fright, and for the time being the matter ended there. It was not until the outbreak of her hysteria that the contracture of the arm set in. In another woman patient, I observed that her speech was interrupted by a peculiar 'clacking' with her tongue, which resembled the cry of a capercaillie. I had been familiar with this symptom for months and regarded it as a *tic*. It was only after I once happened to question her under hypnosis about its origin that I discovered that the noise had first appeared on two occasions. On each of these she had made a firm decision to keep absolutely quiet. This happened once when she was nursing a child of hers who was seriously ill. (Nursing sick people often plays a part in the aetiology of hysteria.) The child had fallen asleep and she was determined not to make any noise that might wake it. But fear that she might make a noise turned into actually making one - an instance of 'hysterical counter-will'; she pressed her lips together and made the clacking noise with her tongue. Many years later the same symptom had arisen a second time, once again when she had made a decision to be absolutely quiet, and it had persisted ever afterwards. A single precipitating cause is often not enough to fixate a symptom; but if this same symptom appears several times accompanied by a particular affect, it becomes fixated and chronic.

One of the commonest symptoms of hysteria is a combination of anorexia and vomiting. I know of a whole number of cases in which the occurrence of this symptom is explained quite simply. Thus in one patient vomiting persisted after she had read a humiliating letter just before a meal and had been violently sick after it. In other cases disgust at food could be quite definitely related to the fact that, owing to the institution of the 'common table', a person may be compelled to eat his meal with someone he detests. The disgust is then transferred from the person to the food. The woman with the *tic* whom I have just mentioned was particularly interesting in this respect. She ate uncommonly little and only under pressure. I learnt from her in hypnosis that a series of psychical traumas had eventually produced this symptom of disgust at food. While she was still a child, her mother, who was very strict, insisted on her eating any meat she had left over at her midday meal two hours later, when it was cold and the fat was all congealed. She did so with great disgust and retained the memory of it; so that later on, when she was no longer subjected to this punishment, she regularly felt disgust at mealtimes. Ten years later she used to sit at table with a relative who was tubercular and kept constantly spitting across the table into the spittoon during meals. A little while later she was obliged to share her meals with a relative who, as she knew, was suffering from a contagious disease. Breuer's patient, again, behaved for some time like someone suffering from hydrophobia. During hypnosis it turned out that she had once unexpectedly seen a dog drinking out of a tumbler of water of hers.

Sleeplessness or disturbed sleep are also symptoms that are usually susceptible to the most precise explanation. Thus, for years on end a woman could never get to sleep till six in the morning. She had for a long time slept in the room adjoining her sick husband, who used to rise at six o'clock. After that hour she had been able to sleep in quiet; and she behaved in the same way once more many years later during a hysterical illness. Another case was that of a man. He was a hysterical patient who had slept very badly for the last twelve years. His sleeplessness, however, was of a quite special sort. In the summer he slept excellently, but in the winter very badly; and in November he slept quite particularly badly. He had no notion what this was due to. Enquiry revealed that in November twelve years earlier he had watched for many nights at the bedside of his son, who was ill with diphtheria.

Breuer's patient, to whom I have so often referred, offered an example of a disturbance of speech. For a long period of her illness she spoke only English and could neither speak nor understand German. This symptom was traced back to an event which had happened before the outbreak of her illness. While she was in a state of great anxiety, she had attempted to pray but could find no words. At last a few words of a child's prayer in English occurred to her. When she fell ill later on, only the English language was at her command.

The determination of the symptom by the psychical trauma is not so transparent in every instance. There is often only what may be described as a 'symbolic' relation between the determining cause and the hysterical symptom. This is especially true of pains. Thus one patient suffered from piercing pains between her eyebrows. The reason was that once when she was a child her grandmother had given her an enquiring, 'piercing' look. The same patient suffered for a time from violent pains in her right heel, for which there was no explanation. These pains, it turned out, were connected with an idea that occurred to the patient when she made her first appearance in society. She was overcome with fear that she might not 'find herself on a right footing'. Symbolizations of this kind were employed by many patients for a whole number of so-called neuralgias and pains. It is as though there were an intention to express the mental state by means of a physical one; and linguistic usage affords a bridge by which this can be effected. In the case, however, of what are after all the typical symptoms of hysteria- such as hemi-anaesthesia, restriction of the visual field, epileptiform convulsions, etc. - a psychical mechanism of this sort cannot be demonstrated. On the other hand this can often be done in respect to the hysterogenic zones.

These examples, which I have chosen out of a number of observations, seem to offer proof that the phenomena of common hysteria can safely be regarded as being on the same pattern as those of traumatic hysteria, with the involvement of psychical, as vs. actual physical trauma and that accordingly every hysteria can be looked upon as traumatic hysteria in the sense of implying a psychical trauma and that every hysterical phenomenon is determined by the nature of the trauma.

The further question which would then have to be answered is as to the nature of the causal connection between the determining factor which we have discovered during hypnosis and the phenomenon which persists subsequently as a chronic symptom. This connection might be of various kinds. It might be of the type that we should describe as a 'releasing' factor. For instance, if someone with a disposition to tuberculosis receives a blow on the knee as a result of which he develops a tubercular inflammation of the joint, the blow is a simple releasing cause. But this is not what happens in hysteria. There is another kind of causation - namely, *direct* causation. We can elucidate this from the picture of a foreign body, which continues to operate unceasingly as a stimulating cause of illness until it is got rid of. *Cessante causa cessat effectus*.¹ Breuer's observation shows us that there is a connection of this latter kind between the psychical trauma and the hysterical phenomenon. For Breuer learnt from his first patient that the attempt at discovering the determining cause of a symptom was at the same time a therapeutic manoeuvre. The moment at which the physician finds out the occasion when the symptom first appeared and the reason for its appearance is also the moment at which the symptom vanishes. When, for instance, the symptom presented by the patient consists in pains, and when we enquire from him under hypnosis as to their origin, he will produce a series of memories in connection with them. If we can succeed in eliciting a really vivid memory in him, and if he sees things before him with all their original actuality, we shall observe that he is completely dominated by some affect. And if we then compel him to put this affect into words, we shall find that, at the same time as he is producing this violent affect, the phenomenon of his pains emerges very markedly once again and that thenceforward the symptom, in its chronic character, disappears. This is how events turned out in all the instances I have quoted. And it was an interesting fact that the memory of this particular event was to an extraordinary degree more vivid than the memory of any others, and that the affect accompanying it was as great, perhaps, as it had been when the event actually occurred. It could only be supposed that the psychical trauma does in fact continue to operate in the subject and maintains the hysterical phenomenon, and that it comes to an end as soon as the patient has spoken about it.

As I have just said, if, in accordance with our procedure, one arrives at the psychical trauma by making enquiries from the patient under hypnosis, one discovers that the memory concerned is quite unusually strong and has retained the whole of its affect. The question now arises how it is that an event which occurred so long ago - perhaps ten or twenty years - can persist in exercising its power over the subject, how it is that these memories have not been subject to the processes of wearing away and forgetting.

¹ ['When the cause ceases the effect ceases']

With a view to answering this question, I should like to begin with a few remarks on the conditions which govern the wearing-away of the contents of our ideational life. We will start from a thesis that may be stated in the following terms. If a person experiences a psychical impression, something in his nervous system which we will for the moment call the sum of excitation is increased. Now in every individual there exists a tendency to diminish this sum of excitation once more, in order to preserve his health. The increase of the sum of excitation takes place along sensory paths, and its diminution along motor ones. So we may say that if anything impinges on someone he reacts in a motor fashion. We can now safely assert that it depends on this reaction how much of the initial psychical impression is left. Let us consider this in relation to a particular example. Let us suppose that a man is insulted, is given a blow or something of the kind. This psychical trauma is linked with an increase in the sum of excitation of his nervous system. There then instinctively arises an inclination to diminish this increased excitation immediately. He hits back, and then feels easier; he may perhaps have reacted adequately—that is, he may have got rid of as much as had been introduced into him. Now this reaction may take various forms. For quite slight increases in excitation, alterations in his own body may perhaps be enough: weeping, abusing, raging, and so on. The more intense the trauma, the greater is the adequate reaction. The most adequate reaction, however is always a deed. But, as an English writer has wittily remarked, the man who first flung a word of abuse at his enemy instead of a spear was the founder of civilization. Thus words are substitutes for deeds, and in some circumstances (e. g. in Confession) the only substitutes. Accordingly, alongside the adequate reaction there is one that is less adequate. If, however, there is no reaction *whatever* to a psychical trauma, the memory of it retains the affect which it originally had. So that if someone who has been insulted cannot avenge the insult either by a retaliatory blow or by a word of abuse, the possibility arises that the memory of the event may call up in him once more the affect which was originally present. An insult that has been repaid, even if only in words, is recollected quite differently from one that has had to be accepted; and linguistic usage characteristically describes an insult that has been suffered in silence as a ‘mortification’. Thus, if for any reason there can be no reaction to a psychical trauma, it retains its original affect, and when someone cannot get rid of the increase in stimulation by ‘abreacting’ it, we have the possibility of the event in question remaining a psychical trauma. Incidentally, a healthy psychical mechanism has other methods of dealing with the affect of a psychical trauma even if motor reaction and reaction by words are denied to it—namely by working it over associatively and by producing contrasting ideas. Even if the person who has been insulted neither hits back nor replies with abuse, he can nevertheless reduce the affect attaching to the insult by calling up such contrasting ideas as those of his own worthiness, of his enemy’s worthlessness, and so on. Whether a healthy man deals with an insult in one way or the other, he always succeeds in achieving the result that the affect which was originally strong in his memory eventually loses intensity and that finally the recollection, having lost its affect, falls a victim to forgetfulness and the process of wearing-away.

Now we have found that in hysterical patients there are nothing but impressions which have not lost their affect and whose memory has remained vivid. It follows, therefore, that these memories in hysterical patients, which have become pathogenic, occupy an exceptional position as regards the wearing-away process; and observation shows that, in the case of all the events which have become determinants of hysterical phenomena, we are dealing with psychical traumas which have not been completely abreacted, or completely dealt with. Thus we may assert that *hysterical patients suffer from incompletely abreacted psychical traumas*.

We find two groups of conditions under which memories become pathogenic. In the first group the memories to which the hysterical phenomena can be traced back have for their content ideas which involved a trauma so great that the nervous system had not sufficient power to deal with it in any way, or ideas to which reaction was impossible for social reasons (this applies frequently to married life); or lastly the subject may simply refuse to react, may not *want* to react to the psychical trauma. In this last case the contents of the hysterical deliria often turn out to be the very circle of ideas which the patient in his normal state has rejected, inhibited and suppressed with all his might. (For instance, blasphemies and erotic ideas occur in the hysterical deliria of nuns.) But in a second group of cases the reason for the absence of a reaction lies not in the content of the psychical trauma but in other circumstances. For we very often find that the content and determinants of hysterical phenomena are events which are in themselves quite trivial, but which have acquired high significance from the fact that they occurred at specially important moments when the patient's predisposition was pathologically increased. For instance, the affect of fright may have arisen in the course of some other severe affect and may on that account have attained such great importance. States of this kind are of short duration and are, as one might say, out of communication with the rest of the subject's mental life. While he is in a state of auto-hypnosis such as this, he cannot get rid associatively of an idea that occurs to him, as he can in a waking state. After considerable experience with these phenomena, we think it probable that in every hysteria we are dealing 'with a rudiment of what is called *'double conscience'*, dual consciousness, and that a tendency to such a dissociation and with it the emergence of abnormal states of consciousness, which we propose to call 'hypnoid', is the basic phenomenon of hysteria.

Let us now consider the manner in which our therapy operates. It falls in with one of the dearest human wishes - the wish to be able to do something over again. Someone has experienced a psychological trauma without reacting to it sufficiently. We get him to experience it a second time, but under hypnosis; and we now compel him to complete his reaction to it. He can then get rid of the idea's affect, which was so to say 'strangled', and when this is done the operation of the idea is brought to an end. Thus we cure - not hysteria but some of its individual symptoms - by causing an unaccomplished reaction to be completed.

You must not suppose, then, that very much has been gained by this for the therapeutics of hysteria. Hysteria, like the neuroses, has its deeper causes; and it is those deeper causes that set limits, which are often very appreciable, to the success of our treatment.

THE NEURO-PSYCHOSES OF DEFENCE
(1894)

Intentionally left blank

THE NEURO-PSYCHOSES OF DEFENCE

(AN ATTEMPT AT A PSYCHOLOGICAL THEORY OF ACQUIRED HYSTERIA, OF MANY PHOBIAS, AND OBSESSIONS AND OF CERTAIN HALLUCINATORY PSYCHOSES)

After making a detailed study of a number of nervous patients suffering from phobias and obsessions, I was led to attempt an explanation of those symptoms; and this enabled me afterwards to arrive successfully at the origin of pathological ideas of this sort in new and different cases. My explanation therefore seems to me to deserve publication and further examination. Simultaneously with this 'psychological theory of phobias and obsessions' my observation of patients resulted in a contribution to the theory of hysteria, or rather to a change in it, which appears to take into account an important characteristic that is common both to hysteria and to the neuroses I have just mentioned. Furthermore, I had occasion to gain insight into what is undoubtedly a form of mental disease, and I found at the same time that the point of view which I had tentatively adopted established an intelligible connection between these psychoses and the two neuroses under discussion. At the end of this paper I shall bring forward a working hypothesis which I have made use of in all three instances.

I

Let me begin with the change which seems to me to be called for in the theory of the hysterical neurosis. Since the fine work done by Pierre Janet, Josef Breuer and others, it may be taken as generally recognized that the syndrome of hysteria, so far as it is as yet intelligible, justifies the assumption of there being a splitting of consciousness, accompanied by the formation of separate psychical groups. Opinions are less settled, however, about the origin of this splitting of consciousness and about the part played by this characteristic in the structure of the hysterical neurosis.

According to the theory of Janet (1892-4 and 1893), the splitting of consciousness is a primary feature of the mental change in hysteria. It is based on an innate weakness of the capacity for psychical synthesis, on the narrowness of the 'field of consciousness (*champ de la conscience*)' which, in the form of a psychical stigma, is evidence of the degeneracy of hysterical individuals.

In contradistinction to Janet's view, which seems to me to admit of a great variety of objections, there is the view put forward by Breuer in our joint communication (Breuer and Freud, 1893). According to him, 'the basis and *sine qua non* of hysteria' is the occurrence of peculiar dream-like states of consciousness with a restricted capacity for association, for which he proposes the name 'hypnoid states'. In that case, the splitting of consciousness is secondary and acquired; it comes about because the ideas which emerge in hypnoid states are cut off from associative communication with the rest of the content of consciousness.

I am now in a position to bring forward evidence of two other extreme forms of hysteria in which it is impossible to regard the splitting of consciousness as primary in Janet's sense. In the first of these forms I was repeatedly able to show that *the splitting in the content of consciousness is the result of an act of will on the part of the patient*; that is to say, it is initiated by an effort of will whose motive can be specified. By this I do not, of course, mean that the patient intends to bring about a splitting of his consciousness. His intention is a different one; but, instead of attaining its aim, it produces a splitting of consciousness.

In the third form of hysteria, which we have demonstrated by means of a psychical analysis of intelligent patients, the splitting of consciousness plays an insignificant part, or perhaps none at all. They are those cases in which what has happened is only that the reaction to traumatic stimuli has failed to occur, and which can also, accordingly, be resolved and cured by 'abreaction'.¹ These are the pure 'retention hysterias'.

As regards the connection with phobias and obsessions, I am only concerned with the second form of hysteria. For reasons which will soon be evident, I shall call this form '*defence* hysteria', using the name to distinguish it from *hypnoid* hysteria and *retention* hysteria. I may also provisionally present my cases of defence hysteria as 'acquired' hysteria, since in them there was no question either of a grave hereditary taint or of an individual degenerative atrophy.

For these patients whom I analysed had enjoyed good mental health up to the moment at which *an occurrence of incompatibility took place in their ideational life* - that is to say, until their ego was faced with an experience, an idea or a feeling which aroused such a distressing affect that the subject decided to forget about it because he had no confidence in his power to resolve the contradiction between that incompatible idea and his ego by means of thought-activity.

In females incompatible ideas of this sort arise chiefly on the soil of sexual experience and sensation; and the patients can recollect as precisely as could be desired their efforts at defence, their intention of 'pushing the thing away', of not thinking of it, of suppressing it. I will give some examples, which I could easily multiply, from my own observation: the case of a girl, who blamed herself because, while she was nursing her sick father, she had thought about a young man who had made a slight erotic impression on her; the case of a governess who had fallen in love with her employer and had resolved to drive this inclination out of her mind because it seemed to her incompatible with her pride; and so on.²

¹ Cf. our joint communication, *ibid.*, 2, 8-9.

² These examples are taken from a volume by Breuer and myself which is still in preparation and which deals in detail with the psychical mechanism of hysteria.

I cannot, of course, maintain that an effort of will to thrust things of this kind out of one's thoughts a pathological act; nor do I know whether and in what way intentional forgetting succeeds in those people who, under the same psychical influences, remain healthy. I only know that this kind of 'forgetting' did not succeed with the patients I analysed, but led to various pathological reactions which produced either hysteria or an obsession or a hallucinatory psychosis. The ability to bring about one of these states - which are all of them bound up with a splitting of consciousness - by means of an effort of will of this sort, is to be regarded as the manifestation of a pathological disposition, although such a disposition is not necessarily identical with individual or hereditary 'degeneracy'.

As regards the path which leads from the patient's effort of will to the onset of the neurotic symptom, I have formed an opinion which may be expressed, in current psychological abstractions, somewhat as follows. The task which the ego, in its defensive attitude, sets itself of treating the incompatible idea as '*non arrivée*' simply cannot be fulfilled by it. Both the memory-trace and the affect which is attached to the idea are there once and for all and cannot be eradicated. But it amounts to an approximate fulfilment of the task if the ego succeeds in *turning this powerful idea into a weak one*, in robbing it of the affect - the sum of excitation - with which it is loaded. The weak idea will then have virtually no demands to make on the work of association. *But the sum of excitation which has been detached from it must be put to another use.*

Up to this point the processes in hysteria, and in phobias and obsessions are the same; from now on their paths diverge. In hysteria, the incompatible idea is rendered innocuous by its *sum of excitation* being *transformed into something somatic*. For this I should like to propose the name of *conversion*.

The conversion may be either total or partial. It proceeds along the line of the motor or sensory innervation which is related - whether intimately or more loosely - to the traumatic experience. By this means the ego succeeds in freeing itself from the contradiction; but instead, it has burdened itself with a mnemonic symbol which finds a lodgement in consciousness, like a sort of parasite, either in the form of an unresolvable motor innervation or as a constantly recurring hallucinatory sensation, and which persists until a conversion in the opposite direction takes place. Consequently the memory-trace of the repressed idea has, after all, not been dissolved; from now on, it forms the nucleus of a second psychical group.

I will only add a few more words to this view of the psycho-physical processes in hysteria. When once such a nucleus for a hysterical splitting-off has been formed at a 'traumatic moment', it will be increased at other moments (which might be called 'auxiliary moments') whenever the arrival of a fresh impression of the same sort succeeds in breaking through the barrier erected by the will, in furnishing the weakened idea with fresh affect and in re-establishing for a time the associative link between the two psychical groups, until a further conversion sets up a defence. The distribution of excitation thus brought about in hysteria usually turns out to be an unstable one. The excitation which is forced into a wrong channel (ie which has been channelled into a somatic innervation) now and then finds its way back to the idea from which it has been detached, and it then compels the subject either to work over the idea associatively or to get rid of it in hysterical attacks - as we see in the familiar contrast between attacks and chronic symptoms. The operation of Breuer's cathartic method lies in leading back the excitation in this way from the somatic to the psychical sphere deliberately, and in then forcibly bringing about a settlement of the contradiction by means of thought-activity and a discharge of the excitation by talking.

If the splitting of consciousness which occurs in acquired hysteria is based upon an act of will, then we have a surprisingly simple explanation of the remarkable fact that hypnosis regularly widens the restricted consciousness of a hysteric and allows access to the psychical group that has been split off. Indeed, we know it as a peculiarity of all states resembling sleep that they suspend the distribution of excitation on which the 'will' of the conscious personality is based.

Thus we see that the characteristic factor in hysteria is not the splitting of consciousness but *the capacity for conversion*, and we may adduce as an important part of the disposition to hysteria - a disposition which in other respects is still unknown - a psycho-physical aptitude for transposing very large sums of excitation into the somatic innervation.

This aptitude does not, in itself, exclude psychical health; and it only leads to hysteria in the event of there being a psychical incompatibility or an accumulation of excitation. In taking this view, Breuer and I are coming closer to Oppenheim's¹ and Strümpell's² well-known definitions of hysteria, and are diverging from Janet, who assigns too great an importance to the splitting of consciousness in his characterization of hysteria.³ The presentation given here may claim to have made intelligible the connection between conversion and the hysterical splitting of consciousness.

¹ According to Oppenheim, hysteria is an intensified expression of motion. The 'expression of emotion', however, represents the amount of psychical excitation which normally undergoes conversion.

² Strümpell maintains that in hysteria the disturbance lies psycho-physical sphere - in the region where the somatic and the mental are linked together.

³ In the second section of his acute paper 'Quelques définitions . . .' Janet has himself dealt with the objection which argues that splitting of consciousness occurs in psychoses and in so-called 'psychasthenia' as well as in hysteria, but in my judgement he has not met it satisfactorily. It is in the main this objection which obliges him to describe hysteria as a form of degeneracy. But he has failed to produce any characteristic which sufficiently distinguishes the splitting of consciousness in hysteria from that in psychoses and similar states.

II

If someone with a disposition lacks the aptitude for conversion, but if, nevertheless, in order to fend off an incompatible idea, he sets about separating it from its affect, then *that affect is obliged to remain in the psychological sphere*. The idea, now weakened, is still left in consciousness, separated from all association. *But its affect, which has become free, attaches itself to other ideas which are not in themselves incompatible; and, thanks to this 'false connection', those ideas turn into obsessional ideas*. This, in a few words, is the psychological theory of obsessions and phobias mentioned at the beginning of this paper.

I will now indicate which of the various elements put forward in this theory can be directly demonstrated and which have been filled in by me. What can be directly demonstrated, apart from the end-product of the process - the obsession - is in the first place the source of the affect which is now in a false connection. In all the cases I have analysed it was the subject's *sexual life* that had given rise to a distressing affect of precisely the same quality as that attaching to his obsession. Theoretically, it is not impossible that this affect should sometimes arise in other fields; I can only report that so far I have not come across any other origin. Moreover, it is easy to see that it is precisely sexual life which brings with it the most copious occasions for the emergence of incompatible ideas.

Furthermore, the most unambiguous statements by the patients give proof of the effort of will, the attempt at defence, upon which the theory lays emphasis; and at least in a number of cases the patients themselves inform us that their phobia or obsession made its first appearance after the effort of will had apparently succeeded in its aim. 'Something very disagreeable happened to me once and I tried very hard to put it away from me and not to think about it any more. I succeeded at last; but then I got this other thing, which I have not been able to get rid of since.' It was with these words that a woman patient confirmed the chief points of the theory I have developed here.

Not everyone who suffers from obsessions is as clear as this about their origin. As a rule, when one draws a patient's attention to the original idea of a sexual kind, the answer is: 'It can't come from that. I didn't think at all much about that. For a moment I was frightened, but I turned my mind away from it and I haven't been troubled by it since.' In this frequent objection we have evidence that the obsession represents a substitute or surrogate for the incompatible sexual idea and has taken its place in consciousness.

Between the patient's effort of will, which succeeds in repressing the unacceptable sexual idea, and the emergence of the obsessional idea, which, though having little intensity in itself, is now supplied with an incomprehensibly strong affect, yawns the gap which the theory here developed seeks to fill. The separation of the sexual idea from its affect and the attachment of the latter to another, suitable but not incompatible idea - these are processes which occur without consciousness. Their existence can only be presumed, but can not be proved by any clinico-psychological analysis. Perhaps it would be more correct to say that these processes are not of a psychical nature at all, that they are physical processes whose psychical consequences present themselves as if what is expressed by the terms 'separation of the idea from its affect' and 'false connection' of the latter had really taken place.

Alongside of the cases which show a sequence between an incompatible sexual idea and an obsessional idea, we find a number of other cases in which obsessional ideas and sexual ideas of a distressing character are present simultaneously. To call the latter 'sexual obsessional ideas' will not do very well, for they lack one essential feature of obsessional ideas: they turn out to be fully justified, whereas the distressing character of ordinary obsessional ideas is a problem for both doctor and patient. So far as I have been able to see my way in cases of this kind, what is happening is that a perpetual defence is going on against sexual ideas that are continually coming up afresh - a piece of work, that is to say, which has not yet come to completion.

So long as the patients are aware of the sexual origin of their obsessions, they often keep them secret. If they do complain about them, they usually express their astonishment that they should be subject to the affect in question - that they should feel anxiety, or have certain impulses, and so on. To the experienced physician, on the contrary, the affect seems justified and comprehensible; what *he* finds noticeable is only that an affect of that kind should be linked with an idea which does not merit it. The affect of the obsession appears to him, in other words, as being *dislodged* or *transposed*; and if he has accepted what has been said in these pages, he will be able, in a number of cases of obsessions, to attempt to *re-translate them into sexual terms*.

To provide this secondary connection for the liberated affect, any idea can be made use of which is either able, from its nature, to be united with an affect of the *quality* in question, or which has certain relations to the incompatible idea which make it seem as though it could serve as a surrogate for it. Thus, for example, liberated anxiety, whose sexual origin must not be remembered by the patient, will seize upon the common primary phobias of mankind about animals, thunderstorms, darkness and so on, or upon things which are unmistakably associated in one way or another with what is sexual - such as micturition, defaecation, or dirtying and contagion generally.

The ego gains much less advantage from choosing *transposition* of affect as a method of defence than from choosing the hysterical *conversion* of psychical excitation into somatic innervation. The affect from which the ego has suffered remains as it was before, unaltered and undiminished, the only difference being that the incompatible idea is kept down and shut out from recollection. The repressed ideas, as in the other case, form the nucleus of a second psychical group, which, I believe, is accessible even without the help of hypnosis. If phobias and obsessions are unaccompanied by the striking symptoms which characterize the formation of an independent psychical group in hysteria, this is doubtless because in their case the whole alteration has remained in the psychical sphere and the relationship between psychical excitation and somatic innervation has undergone no change.

To illustrate what has been said about obsessions, I will give a few examples which are, I imagine, of a typical kind:

(1) A girl suffered from obsessional self-reproaches. If she read something in the papers about coiners, the thought would occur to her that she, too, had made counterfeit money; if a murder had been committed by an unknown person, she would ask herself anxiously whether it was not she who had done the deed. At the same time she was perfectly conscious of the absurdity of these obsessional reproaches. For a time, this sense of guilt gained such an ascendancy over her that her powers of criticism were stifled and she accused herself to her relatives and her doctor of having really committed all these crimes. (This was an example of a psychosis through simple intensification - an '*Überwältigungspsychose*'.) Close questioning then revealed the source from which her sense of guilt arose. Stimulated by a chance voluptuous sensation, she had allowed herself to be led astray by a woman friend into masturbating, and had practised it for years, fully conscious of her wrong-doing and to the accompaniment of the most violent, but, as usual, ineffective self-reproaches. An excessive indulgence after going to a ball had produced the intensification that led to the psychosis. After a few months of treatment and the strictest surveillance, the girl recovered.

(2) Another girl suffered from the dread of being overcome by the need to urinate, and of being unable to avoid wetting herself, ever since a need of this kind had in fact once obliged her to leave a concert hall during the performance. By degrees this phobia had made her completely incapable of enjoying herself or of going into society. She only felt well if she knew that there was a W. C. near at hand which she could reach unobtrusively. There was no question of any organic complaint which might justify this mistrust in her power to control her bladder; when she was at home, in quiet conditions, or at night, the need to urinate did not arise. A detailed examination showed that the need had occurred first in the following circumstances. In the concert hall a gentleman to whom she was not indifferent had taken a seat not far from her. She began to think about him and to imagine herself sitting beside him as his wife. During this erotic reverie she had the bodily sensation which is to be compared with an erection in a man, and which in her case - I do not know if this is always so - ended with a slight need to urinate. She now became greatly frightened by the sexual sensation (to which she was normally accustomed) because she had resolved within herself to combat this particular liking, as well as any other she might feel; and next moment the affect had become transferred on to the accompanying need to urinate and compelled her after an agonizing struggle to leave the hall. In her ordinary life she was so prudish that she had an intense horror of everything to do with sex and could not contemplate the thought of ever marrying. On the other hand, she was so hyperaesthetic sexually that during every erotic reverie, in which she readily indulged, the same voluptuous sensation appeared. The erection was each time accompanied by the need to urinate, though without its making any impression on her until the scene in the concert hall. The treatment led to an almost complete control over her phobia.

(3) A young married woman who, in five years of marriage, had had only one child, complained to me of an obsessional impulse to throw herself out of the window or from the balcony, and also of a fear which seized her when she saw a sharp knife, of stabbing her child with it. She admitted that marital intercourse seldom occurred, and only subject to precautions against conception, but she did not miss it, she said, as hers was not a sensual nature. At this point I ventured to tell her that at the sight of a man she had erotic ideas and that she had therefore lost confidence in herself and regarded herself as a depraved person, capable of anything. The translation back of the obsessional idea into sexual terms was successful. In tears, she at once confessed the long-concealed poverty of her marriage; and later she told me also of distressing ideas of an unmodified sexual character such as the often-recurring sensation of something forcing itself under her skirt.

I have turned observations of this kind to account in my therapeutic work by leading back the attention of patients with phobias and obsessions to the repressed sexual ideas in spite of all their protestations, and, wherever possible, by stopping up the sources from which those ideas sprang. I cannot, of course, assert that *all* phobias and obsessions arise in the manner I have shown here. In the first place, my experience of them includes only a limited number compared with the frequency of these neuroses; and in the second place, I myself am aware that such 'psychasthenic' symptoms, as Janet terms them, are not all equivalent.¹ There are, for instance, purely hysterical phobias. Nevertheless, I think that it will be possible to show the presence of the mechanism of transposition of affect in the great majority of phobias and obsessions, and I would therefore urge that these neuroses, which are found in an isolated state as often as in combination with hysteria or neurasthenia, should not be thrown into a heap along with common neurasthenia, for the basic symptoms of which there is no ground at all to assume a *psychical* mechanism.

¹ The group of typical phobias, of which agoraphobia is a typical model, cannot be traced back to the psychical mechanism described above; on the contrary, the mechanism of agoraphobia differs from that of obsessions proper, and of the phobias that are reducible to them, in one decisive point. There is no repressed idea from which the anxiety affect might have been separated off. The anxiety of these phobias has another origin.

III

In both the instances considered so far, defence against the incompatible idea was effected by separating it from its affect; the idea itself remained in consciousness, even though weakened and isolated. There is, however, a much more energetic and successful kind of defence. Here, the ego rejects the incompatible idea together with its affect and behaves as if the idea had never occurred to the ego at all. *But from the moment at which this has been successfully done the subject is in a psychosis, which can only be classified as 'hallucinatory confusion'.* A single example may serve to illustrate this statement:

A girl had given her first impulsive affection to a man, and firmly believed that he returned her love. In fact, she was wrong; the young man had a different motive for visiting the house. Disappointments were not wanting. At first she defended herself against them by effecting a hysterical conversion of the experiences in question and thus preserved her belief that one day he would come and ask her hand. But at the same time she felt unhappy and ill, because the conversion was incomplete and because she was continually being met by fresh painful impressions. Finally, in a state of great tension, she awaited his arrival on a particular day, the day of a family celebration. But the day wore on and he did not appear. When all the trains by which he could arrive had come and gone, she passed into a state of hallucinatory confusion: he had arrived, she heard his voice in the garden, she hurried down in her night-dress to receive him. From that time on she lived for two months in a happy dream, whose content was that he was there, always at her side, and that everything was as it had been before (before the time of the disappointments which she had so laboriously fended off). Her hysteria and her depression of spirits were overcome. During her illness she was silent about the whole latter period of doubt and suffering; she was happy so long as she was left undisturbed, and she broke out in fury only when some rule of conduct insisted on by those around her hindered her in something which seemed to her to follow quite logically from her blissful dream. This psychosis, which had been unintelligible at the time, was explained ten years later with the help of a hypnotic analysis.

The fact to which I now wish to call attention is that the content of a hallucinatory psychosis of this sort *consists precisely in the accentuation of the idea* which was threatened by the precipitating cause of the onset of the illness. One is therefore justified in saying that the ego has fended off the incompatible idea through a flight into psychosis. The process by which this has been achieved once more eludes the subject's self perception, as it eludes psychologico-clinical analysis. It must be regarded as the expression of a pathological disposition of a fairly high degree and it may be described more or less as follows. The ego breaks away from the incompatible idea; but the latter is inseparably connected with a piece of reality, so that, in so far as the ego achieves this result, it, too, has detached itself wholly or in part from reality. In my opinion this latter event is the condition under which the subject's ideas receive the vividness of hallucinations; and thus when the defence has been successfully carried out he finds himself in a state of hallucinatory confusion.

I have only very few analyses of psychoses of this sort at my disposal. But I think we have to do here with a type of psychical illness which is very frequently employed. For no insane asylum is without what must be regarded as analogous examples - the mother who has fallen ill from the loss of her baby, and now rocks a piece of wood unceasingly in her arms, or the jilted bride who, arrayed in her wedding-dress, has for years been waiting for her bridegroom.

It is perhaps not superfluous to point out that the three methods of defence here described and, along with them, the three forms of illness to which those methods lead, may be combined in the same person. The simultaneous appearance of phobias and hysterical symptoms which is so often observed in practice is one of the factors which render it difficult to separate hysteria clearly from other neuroses and which make it necessary to set up the category of 'mixed neuroses'. It is true that hallucinatory confusion is not often compatible with a persistence of hysteria, nor, as a rule, of obsessions. On the other hand, it is not rare for a psychosis of defence episodically to break through the course of a hysterical or mixed neurosis.

I should like, finally, to dwell for a moment on the working hypothesis which I have made use of in this exposition of the neuroses of defence. I refer to the concept that in mental functions something is to be distinguished - a quota of affect or sum of excitation - which possesses all the characteristics of a quantity (though we have no means of measuring it), which is capable of increase, diminution, displacement and discharge, and which is spread over the memory-traces of ideas somewhat as an electric charge is spread over the surface of a body.

This hypothesis which, incidentally, already underlies our theory of 'abreaction' in our 'Preliminary Communication' (1893a), can be applied in the same sense as physicists apply the hypothesis of a flow of electric fluid. It is provisionally justified by its utility in co-ordinating and explaining a great variety of psychical states.

OBSESSIONS AND PHOBIAS
THEIR PSYCHICAL MECHANISM AND THEIR AETIOLOGY
(1895)

Intentionally left blank

OBSESSIONS AND PHOBIAS

THEIR PSYCHICAL MECHANISM AND THEIR AETIOLOGY

I shall begin by challenging two assertions which are often found repeated in regard to the syndromes 'obsessions' and 'phobias'. It must be said, first, that they cannot be included under neurasthenia proper, since the patients afflicted with these symptoms are no more often neurasthenics than not; and secondly, that we are not justified in regarding them as the effect of mental degeneracy, because they are found in persons no more degenerate than the majority of neurotics in general, because they sometimes improve, and sometimes, indeed, we even succeed in curing them.¹

Obsessions and phobias are separate neuroses, with a special mechanism and aetiology which I have succeeded in demonstrating in a certain number of cases, and which, I hope, will prove similar in a good number of fresh cases.

As regards classification of the subject, I propose in the first place to exclude a group of intense obsessions which are nothing but memories, unaltered images of important events. As an example, I may cite Pascal's obsession: he always thought he saw an abyss on his left hand 'after he had nearly been thrown into the Seine in his coach'. Such obsessions and phobias, which might be called *traumatic*, are allied to the symptoms of hysteria.

Apart from this group we must distinguish: (a) true obsessions (b) phobias. The essential difference between them is the following:

Two constituents are found in every obsession: (1) an idea that forces itself upon the patient (2) an associated emotional state. Now in the group of phobias this emotional state is always one of 'anxiety', while in true obsessions other emotional states, such as doubt, remorse, or anger, may occur just as well as anxiety. I will first attempt to explain the really remarkable psychological mechanism of true obsessions, a mechanism quite different from that of the phobias.

¹ I am very glad to find that the authors of the most recent work on this subject express opinions very similar to mine. Cf. Gélinau (1894), and Hack Tuke (1894).

I

In many true obsessions it is quite plain that the emotional state is the principal thing, since that state persists unchanged while the idea associated with it varies. The girl in Case 1 quoted below, for example, felt remorse in some degree for all sorts of reasons - for having stolen, for having ill-treated her sisters, for having made counterfeit money, etc. People who doubt have many doubts at the same time or in succession. It is the emotional state which remains constant in them; the idea changes. In other cases the idea, too, seems fixated, as in Case 4, of the girl who pursued the servants in the house with an incomprehensible hatred, though constantly changing the individual object.

Now a careful psychological analysis of these cases shows that *the emotional state, as such, is always justified*. The girl in Case 1, who suffered from remorse, had good reasons for it; the women in Case 3 who doubted their powers of resistance to temptation knew very well why. The girl in Case 4, who detested servants, had good reasons for complaining, etc. Only, and it is in these two characteristics that the pathological mark lies, (1) *the emotional state persists indefinitely*, and, (2) *the associated idea is no longer the appropriate original one, related to the aetiology of the obsession, but is one which replaces it, a substitute for it*.

The proof of this is the fact that we can always find in the previous history of the patient, *at the beginning of the obsession*, the original idea that has been replaced. The replaced ideas all have common attributes; they correspond to really distressing experiences in the subject's sexual life which he is striving to forget. He succeeds merely in replacing the incompatible idea by another ill-adapted for being associated with the emotional state, which for its part remains unchanged. It is this *mésalliance* between the emotional state and the associated idea that accounts for the absurdity so characteristic of obsessions.

I will now bring forward my observations and conclude with an attempt at a theoretical explanation.

Case 1. A girl reproached herself for things which she knew were absurd: for having stolen, for having made counterfeit money, for being involved in a conspiracy, etc., according to what she happened to have been reading during the day.

Reinstatement of the replaced idea: She reproached herself with the masturbation she had been practising in secret without being able to renounce it. She was cured by careful surveillance which prevented her from masturbating.

Case 2. A young man, a medical student, suffered from an analogous obsession. He reproached himself for all sorts of immoral acts: for having killed his cousin, for having violated his sister, for having set fire to a house, etc. He got to the point of having to turn round in the street to see whether he had not killed the last passer-by.

Reinstatement: He had been much affected by reading in a quasi-medical book that masturbation, to which he was addicted, destroyed one's morale.

Case 3. Several women complained of an obsessional impulse to throw themselves out of the window, to stab their children with knives, scissors, etc.

Reinstatement: Obsessions based on typical temptations. These were women who, not being at all satisfied in marriage, had to struggle against the desires and voluptuous ideas that constantly troubled them at the sight of other men.

Case 4. A girl who was perfectly sane and very intelligent displayed an uncontrollable hatred against the servants in the house. It had been started in connection with an impertinent servant, and had been transferred from servant to servant, to an extent that made housekeeping impossible. The feeling was a mixture of hate and disgust. She gave as a reason for it that the coarseness of these girls spoilt her idea of love.

Reinstatement: This girl had been an involuntary witness of a love-scene in which her mother had taken part. She had hidden her face, had stopped up her ears, and had done her utmost to forget it, as it disgusted her and would have made it impossible for her to remain with her mother, whom she loved tenderly. She succeeded in her efforts, but her anger at her idea of love having been defiled persisted within her, and this emotional state soon linked itself to the idea of a person who could take her mother's place.

Case 5. A girl had become almost completely isolated on account of an obsessional fear of incontinence of urine. She could no longer leave her room or receive visitors without having urinated a number of times. When she was at home or entirely alone the fear did not trouble her.

Reinstatement. It was an obsession based on temptation or mistrust. She did not mistrust her bladder, but her resistance to erotic impulses. The origin of the obsession shows this clearly. Once, at the theatre, on seeing a man who attracted her, she had felt an erotic desire, accompanied (as spontaneous pollutions in women always are) by a desire to urinate. She was obliged to leave the theatre, and from that moment on she was a prey to the fear of having the same sensation, but the desire to urinate had replaced the erotic one. She was completely cured.

Although the cases I have enumerated show varying degrees of complexity, they have this in common: the original (incompatible) idea has been replaced by another idea, the substituted idea. In the cases which I now append, the original idea has been replaced, but not by another idea; it has been replaced by acts or impulses which originally served as measures of *relief* or as *protective* procedures, and are now grotesquely associated with an emotional state which does not fit them, but which has persisted unchanged, and which has remained as justifiable as it was at its origin.

Case 6. *Obsessional arithmomania.* - A woman found herself obliged to count the boards in the floor, the steps in the stair case, etc. - acts which she performed in a ridiculous state of anxiety.

Reinstatement. She had begun the counting in order to distract her mind from obsessional ideas (of temptation). She had succeeded in doing so, but the impulse to count had replaced the original obsession.

Case 7. *Obsessional brooding and speculating*. - A woman suffered from attacks of this obsession which ceased only when she was ill, and then gave place to hypochondriacal fears. The theme of her worry was always a part or function of her body; for example, respiration: 'Why must I breathe? Suppose I didn't want to breathe?' etc.

Reinstatement. At the very beginning she had suffered from the fear of becoming insane, a hypochondriacal phobia common enough among women who are not satisfied by their husbands, as she was not. *To assure herself that she was not going mad*, that she was still in possession of her mental faculties, she had begun to ask herself questions and concern herself with serious problems. This calmed her at first, but with time the habit of speculation replaced the phobia. For more than fifteen years, periods of fear (pathophobia) and of obsessive speculating had alternated in her.

Case 8. *Folie du doute*. - Several cases showed the typical symptoms of this obsession but were explained very simply. These persons had suffered or were still suffering from various obsessions, and the knowledge that the obsessions had disturbed all their acts and had many times interrupted their train of thought provoked a legitimate doubt about the reliability of their memory. The confidence of each one of us is shaken, and we all of us have to re-read a letter or repeat a calculation if our attention has been distracted several times during the performance of the act. Doubt is a quite logical result when obsessions are present.

Case 9. *Folie du doute (Hesitation)*. - The girl in Case 4 had become extremely slow in the performance of all her everyday actions, particularly in her toilet. She took hours to tie her shoe laces or to clean her finger-nails. By way of explanation she said she could not make her toilet while the obsessional ideas were occupying her, nor immediately afterwards. As a result, she had become accustomed to wait a definite length of time after each return of the obsessional idea.

Case 10. *Folie du doute*. (*Fear of scraps of paper*.) - A young woman had suffered from scruples after having written a letter; at the same time she collected all the pieces of paper she saw. She explained this by confessing to a love which she had formerly refused to admit. As a result of constantly repeating her lover's name, she was seized with a fear that the name might have slipped off the end of her pen, that she might have written it upon some scrap of paper in a pensive moment.¹

Case 11. *Mysophobia*. - A woman kept washing her hands constantly and touched door-handles only with her elbow.

Reinstatement: It was the case of Lady Macbeth. The washing was symbolic, designed to replace by physical purity the moral purity which she regretted having lost. She tormented herself with remorse for conjugal infidelity, the memory of which she had resolved to banish from her mind. In addition, she used to wash her genitals.

As regards the theory of this process of substitution, I will content myself with answering three questions that arise here.

(1) How can the substitution come about?

It seems to be the expression of a special inherited mental disposition. At any rate, 'similar heredity' is often enough found in obsessional cases, and in hysteria. Thus the patient in Case 2 told me that his father had suffered from similar symptoms. He once introduced me to a first cousin who had obsessions and a *tic convulsif*, and to his sister's daughter, aged eleven, who already gave evidence of obsessions (probably of remorse).

(2) What is the motive for the substitution?

I think it may be regarded as an act of defence (*Abwehr*) of the ego against the incompatible idea. Among my patients there are some who remember a deliberate effort to banish the distressing idea or recollection from the field of consciousness. (See Cases 3, 4, 11.) In other cases the expulsion of the incompatible idea is brought about which has left no trace in the patient's memory.

(3) Why does the emotional state that is associated with the obsessional idea persist indefinitely instead of vanishing like other states of our ego?

This question may be answered by reference to the theory of the genesis of hysterical symptoms developed by Breuer and myself.¹ Here I will only remark that, by the very fact of the substitution, the disappearance of the emotional state is rendered impossible.

¹ Cf. the German popular song:

Auf jedes weisse Blatt Papier möcht' ich es schreiben:
Dein ist mein Herz und soll es ewig, ewig bleiben.

II

In addition to these two groups of true obsessions there is the class of 'phobias', which must now be considered. I have already mentioned the great difference between obsessions and phobias: that in the latter the emotion is always one of anxiety, fear. I might add that obsessions are varied and more specialized, phobias are more monotonous and typical. But this distinction is not of capital importance.

Among the phobias, also, two groups may be differentiated, according to the nature of the object feared: (1) common phobias, an exaggerated fear of things that everyone detests or fears to some extent: such as night, solitude, death, illnesses, dangers in general, snakes, etc. (2) contingent phobias, the fear of special conditions that inspire no fear in the normal man; for example, agoraphobia and the other phobias of locomotion. It is interesting to note that these phobias have not the obsessive feature that characterizes true obsessions and the common phobias. The emotional state appears in their instance only under special conditions which the patient carefully avoids.

The mechanism of phobias is entirely different from that of obsessions. Substitution is no longer the predominant feature in the former; psychological analysis reveals no incompatible, replaced idea in them. Nothing is ever found but *the emotional state of anxiety* which, by a kind of selective process, brings up all the ideas adapted to become the subject of a phobia. In the case of agoraphobia, etc., we often find *the recollection of an anxiety attack*; and what the patient actually fears is the occurrence of such an attack under the special conditions in which he believes he cannot escape it.

¹ 'On the Psychical Mechanism of Hysterical Phenomena' (1893a)

The anxiety belonging to this emotional state, which underlies all phobias, is not derived from any memory; we may well wonder what the source of this powerful condition of the nervous system can be.

I hope to be able to demonstrate, on another occasion, that there is reason to distinguish a special neurosis, the 'anxiety neurosis', of which the chief symptom is this emotional state. I shall then enumerate its various symptoms and insist on the necessity for differentiating this neurosis from neurasthenia, with which it is now confused. *Phobias*, then, *are part of the anxiety neurosis*, and are almost always accompanied by other symptoms of the same group.

The anxiety neurosis, too, *has a sexual origin* as far as I can see, but it does not attach itself to ideas taken from sexual life; properly speaking, it has no psychical mechanism. Its specific cause is the accumulation of sexual tension, produced by abstinence or by unconsummated sexual excitation (using the term as a general formula for the effects of, of relative impotence in the husband, of excitation without satisfaction in engaged couples, of enforced abstinence, etc.).

It is under such conditions, extremely frequent in modern society, especially among women, that anxiety neurosis (of which phobias are a psychical manifestation) develops.

In conclusion I may point out that combinations of a phobia and an obsession proper may co-exist, and that indeed this is a very frequent occurrence. We may find that a phobia had developed at the beginning of the disease as a symptom of anxiety neurosis. The idea which constitutes the phobia and which is associated with the state of fear may be replaced by another idea or rather by the *protective procedure* that seemed to relieve the fear. Case 7 (obsessive speculating) presents a neat example of this group: a *phobia along with a true substitutive obsession*.

ON THE GROUNDS FOR DETACHING A PARTICULAR SYNDROME FROM NEURASTHENIA
UNDER THE DESCRIPTION 'ANXIETY NEUROSIS'

(1895)

Intentionally left blank

ON THE GROUNDS FOR DETACHING A PARTICULAR SYNDROME FROM NEURASTHENIA UNDER THE DESCRIPTION 'ANXIETY NEUROSIS'

It is difficult to make any statement of general validity about neurasthenia, so long as we use that name to cover all the things which Beard has included under it. In my opinion, it can be nothing but a gain to neuropathology if we make an attempt to separate from neurasthenia proper all those neurotic disturbances in which, on the one hand, the symptoms are more firmly linked to one another than to the typical symptoms of neurasthenia (such as intracranial pressure, spinal irritation, and dyspepsia with flatulence and constipation); and which, on the other hand, exhibit essential differences in their aetiology and mechanism from the typical neurasthenic neurosis. If we accept this plan, we shall soon obtain a fairly uniform picture of neurasthenia. We shall then be in a position to differentiate from genuine neurasthenia more sharply than has hitherto been possible various pseudo-neurasthenias (such as the clinical picture of the organically determined nasal reflex neurosis, the nervous disorders of the cachexias and arteriosclerosis, the preliminary stages of general paralysis of the insane, and of some psychoses). Further, it will be possible - as Möbius has proposed - to eliminate some of the *status nervosi* of hereditarily degenerate individuals; and we shall also discover reasons why a number of neuroses which are to-day described as neurasthenia - in particular, neuroses of an intermittent or periodical nature - ought rather to be included under melancholia. But the most marked change of all will be introduced if we decide to detach from neurasthenia the syndrome which I propose to describe in the following pages and which satisfies especially fully the conditions set out above. The symptoms of this syndrome are clinically much more closely related to one another than to those of genuine neurasthenia (that is, they frequently appear together and they replace one another in the course of the illness); and both the aetiology and the mechanism of this neurosis are fundamentally different from the aetiology and mechanism of genuine neurasthenia as it will be left after this separation has been effected.

I call this syndrome 'anxiety neurosis', because all its components can be grouped round the chief symptom of anxiety, because each one of them has a definite relationship to anxiety. I thought that this view of the symptoms of anxiety neurosis had originated with me, until an interesting paper by E. Hecker (1893) came into my hands, in which I found the same interpretation expounded with all the clarity and completeness that could be desired.¹ Nevertheless, although Hecker recognizes certain symptoms as equivalents or rudiments of an anxiety attack, he does not separate them from the domain of neurasthenia, as I propose to do. But this is evidently due to his not having taken into account the difference between the aetiological determinants in the two cases. When this latter difference is recognized there is no longer any necessity for designating anxiety symptoms by the same name as genuine neurasthenic ones; for the principal purpose of giving what is otherwise an arbitrary name is to make it easier to lay down general statements.

¹ Anxiety is actually brought forward as one of the principal symptoms of neurasthenia in a work by Kaan (1893).

I

THE CLINICAL SYMPTOMATOLOGY OF ANXIETY NEUROSIS

What I call 'anxiety neurosis' may be observed in a completely developed form or in a rudimentary one, in isolation or combined with other neuroses. It is of course the cases which are in some degree complete and at the same time isolated which give particular support to the impression that anxiety neurosis is a clinical entity. In other cases, where the syndrome corresponds to a 'mixed neurosis', we are faced with the task of picking out and separating those symptoms which belong, not to neurasthenia or hysteria, and so on, but to anxiety neurosis.

The clinical picture of anxiety neurosis comprises the following symptoms:

(1) *General irritability*. This is a common nervous symptom and as such belongs to many *status nervosi*. I mention it here because it invariably appears in anxiety neurosis and is important theoretically. Increased irritability always points to an accumulation of excitation or an inability to tolerate such an accumulation - that is, to an *absolute* or a *relative* accumulation of excitation. One manifestation of this increased irritability seems to me to deserve special mention; I refer to *auditory hyperaesthesia*, to an oversensitiveness to noise - a symptom which is undoubtedly to be explained by the innate intimate relationship between auditory impressions and fright. Auditory hyperaesthesia frequently turns out to be a cause of sleeplessness, of which more than one form belongs to anxiety neurosis.

(2) *Anxious expectation*. I cannot better describe the condition I have in mind than by this name and by adding a few examples. A woman, for instance, who suffers from anxious expectation will think of influenzal pneumonia every time her husband coughs when he has a cold, and, in her mind's eye, will see his funeral go past; if, when she is coming towards the house, she sees two people standing by her front door, she cannot avoid thinking that one of her children has fallen out of the window; when she hears the bell ring, it is someone bringing news of a death, and so on - while on all these occasions there has been no particular ground for exaggerating a mere possibility.

Anxious expectation, of course, shades off imperceptibly into normal anxiety, comprising all that is ordinarily spoken of as anxiousness - or a tendency to take a pessimistic view of things; but at every opportunity it goes beyond a plausible anxiousness of this kind, and it is frequently recognized by the patient himself as a kind of compulsion. For one form of anxious expectation - that relating to the subject's own health - we may reserve the old term *hypochondria*. The height reached by the hypochondria is not always parallel with the general anxious expectation; it requires as a precondition the existence of paraesthesias and distressing bodily sensations. Thus hypochondria is the form favoured by genuine neurasthenics when, as often happens, they fall victims to anxiety neurosis.

A further expression of anxious expectation is no doubt to be found in the inclination to *moral anxiety*, to scrupulousness and pedantry - an inclination which is so often present in people with more than the usual amount of moral sensitiveness and which likewise varies from the normal to an exaggerated form in *doubting mania*.

Anxious expectation is the nuclear symptom of the neurosis. It openly reveals, too, a portion of the theory of the neurosis. We may perhaps say that here a *quantum of anxiety in a freely floating state*, which, where there is expectation, controls the choice of ideas and is always ready to link itself with any suitable ideational content.

(3) But anxiousness - which, though mostly latent as regards consciousness, is constantly lurking in the background - has other means of finding expression besides this. It can suddenly break through into consciousness without being aroused by a train of ideas, and thus provoke an anxiety attack. An anxiety attack of this sort may consist of the feeling of anxiety, alone, without any associated idea, or accompanied by the interpretation that is nearest to hand, such as ideas of the extinction of life, or of a stroke, or of a threat of madness; or else some kind of paraesthesia (similar to the hysterical aura) may be combined with the feeling of anxiety, or, finally, the feeling of anxiety may have linked to it a disturbance of one or more of the bodily functions - such as respiration, heart action, vasomotor innervation or glandular activity. From this combination the patient picks out in particular now one, now another, factor. He complains of 'spasms of the heart', 'difficulty in breathing', 'outbreaks of sweating', 'ravenous hunger', and such like; and, in his description, the feeling of anxiety often recedes into the background or is referred to quite unrecognizably as 'being unwell', 'feeling uncomfortable', and so on.

(4) Now it is an interesting fact, and an important one from a diagnostic point of view, that the proportion in which these elements are mixed in an anxiety attack varies to a remarkable degree, and that almost every accompanying symptom alone can constitute the attack just as well as can the anxiety itself. There are consequently *rudimentary anxiety attacks* and *equivalents of anxiety attacks*, all probably having the same significance, which exhibit a great wealth of forms that has as yet been little appreciated. A closer study of these larval anxiety-states (as Hecker calls them) and their diagnostic differentiation from other attacks should soon become a necessary task for neuropathologists.

I append here a list which includes only those forms of anxiety attack which are known to me:-

(a) Anxiety attacks accompanied by disturbances of the *heart action*, such as palpitation, either with transitory arrhythmia or with tachycardia of longer duration which may end in serious weakness of the heart and which is not always easily differentiated from organic heart affection; and, again, pseudo-angina pectoris - diagnostically a delicate subject!

(b) Anxiety attacks accompanied by *disturbances of respiration*, several forms of nervous dyspnoea, attacks resembling asthma, and the like. I would emphasize that even these attacks are not always accompanied by recognizable anxiety.

(c) Attacks of *sweating*, often at night.

(d) Attacks of *tremor* and *shivering* which are only too easily confused with hysterical attacks.

(e) Attacks of *ravenous hunger*, often accompanied by vertigo.

(f) Diarrhoea coming on in attacks.

(g) Attacks of locomotor *vertigo*.

(h) Attacks of what are known as *congestions*, including practically everything that has been termed vasomotor neurasthenia.

(i) Attacks of *paraesthesias*. (But these seldom occur without anxiety or a similar feeling of discomfort.)

(5) *Waking up at night in a fright* (the *pavor nocturnus* of adults), which is usually combined with anxiety, dyspnoea, sweating and so on, is very often nothing else than a variant of the anxiety attack. This disturbance is the determinant of a second form of sleeplessness within the field of anxiety neurosis. I have become convinced, moreover, that the *pavor nocturnus* of children, too, exhibits a form which belongs to anxiety neurosis. The streak of hysteria about it, the linking of the anxiety with the reproduction of an appropriate experience or a dream, causes the *pavor nocturnus* of children to appear as something special. But the *pavor* can also emerge in a pure form, without any dream or recurring hallucination.

(6) '*Vertigo*' occupies a prominent place in the group of symptoms of anxiety neurosis. In its mildest form it is best described as 'giddiness'; in its severer manifestations, as 'attacks of vertigo' (with or without anxiety), it must be classed among the gravest symptoms of the neurosis. The vertigo of anxiety neurosis is not rotatory nor does it especially affect certain planes or directions, like Meniere's vertigo. It belongs to the class of locomotor or co-ordinatory vertigo, as does the vertigo in oculomotor paralysis. It consists in a specific state of discomfort, accompanied by sensations of the ground rocking, of the legs giving way and of its being impossible to stand up any more; while the legs feel as heavy as lead and tremble or the knees bend. This vertigo never leads to a fall. On the other hand, I should like to state that an attack of vertigo of this kind may have its place taken by a profound fainting fit. Other conditions in the nature of fainting occurring in anxiety neurosis appear to depend upon cardiac collapse.

Attacks of vertigo are not seldom accompanied by the worst sort of anxiety, often combined with cardiac and respiratory disturbances. According to my observations, vertigo produced by heights, mountains and precipices is also often present in anxiety neurosis. Furthermore, I am not sure whether it is not also right to recognize alongside of this a *vertigo a stomacho laeso*.

(7) On the basis of chronic anxiousness (anxious expectation) on the one hand, and a tendency to anxiety attacks accompanied by vertigo on the other, two groups of typical phobias develop, the first relating to general physiological dangers, the second relating to locomotion. To the first group belong fear of snakes, thunderstorms, darkness, vermin, and so on, as well as the typical moral over-scrupulousness and forms of doubting mania. Here the available anxiety is simply employed to reinforce aversions which are instinctively implanted in everyone. But as a rule a phobia which acts in an obsessional manner is only formed if there is added to this the recollection of an experience in which the anxiety was able to find expression as, for instance, after the patient has experienced a thunderstorm in the open. It is a mistake to try to explain such cases as being simply a persistence of strong impressions; what makes these experiences significant and the memory of them lasting is, after all, only the anxiety which was able to emerge at the time and which can similarly emerge now. In other words, such impressions remain powerful only in people with 'anxious expectation'.

The other group includes *agoraphobia* with all its accessory forms, the whole of them characterized by their relation to locomotion. We frequently find that this phobia is based on an attack of vertigo that has preceded it; but I do not think that one can postulate such an attack in every case. Occasionally we see that after a first attack of vertigo without anxiety, locomotion, although henceforward constantly accompanied by a sensation of vertigo, still continues to be possible without restriction; but that, under certain conditions - such as being alone or in a narrow street - when once anxiety is added to the attack of vertigo, locomotion breaks down.

The relation of these phobias to the phobias of obsessional neurosis, whose mechanism I made clear in an earlier paper¹ in this periodical, is of the following kind. What they have in common is that in both an idea becomes obsessional as a result of being attached to an available affect. The mechanism of *transposition of affect* thus holds good for both kinds of phobia. But in the phobias of anxiety neurosis (1) this affect always has the same colour, which is that of anxiety; and (2) the affect does not originate in a repressed idea, but turns out to be *not further reducible by psychological analysis, nor amenable to psychotherapy*. The mechanism of *substitution*, therefore, does not hold good for the phobias of anxiety neurosis.

Both kinds of phobias (and also obsessions) often appear side by side; although the *atypical* phobias, which are based on obsessions, need not necessarily spring from the soil of anxiety neurosis. A very frequent and apparently complicated mechanism makes its appearance if, in what was originally a simple phobia belonging to an anxiety neurosis, the content of the phobia is replaced by another idea, so that the substitute is *subsequent* to the phobia. What are most often employed as substitutes are the '*protective measures*' that were originally used to combat the phobia. Thus, for instance, 'brooding mania' arises from the subject's endeavours to disprove that he is mad, as his hypochondriacal phobia maintains; the hesitations and doubt, and still more the repetitions, of *folie du doute* arise from a justifiable doubt about the certainty of one's own train of thought, since one is conscious of its persistent disturbance by ideas of an obsessional sort, and so on. We can therefore assert that many syndromes, too, of obsessional neurosis, such as *folie du doute* and the like, are also to be reckoned, clinically if not conceptually, as belonging to anxiety neurosis.²

¹ 'The Neuro-Psychoses of Defence' (1894a).

² See 'Obsessions and Phobias' (1895c).

(8) The digestive activities undergo only a few disturbances in anxiety neurosis; but these are characteristic ones. Sensations such as an inclination to vomit and nausea are not rare, and the symptom of ravenous hunger may, by itself or in conjunction with other symptoms (such as congestions), give rise to a rudimentary anxiety attack. As a chronic change, analogous to anxious expectation, we find an inclination to diarrhoea, and this has been the occasion of the strangest diagnostic errors. Unless I am mistaken, it is this diarrhoea to which Möbius (1894) has drawn attention recently in a short paper. I suspect, further, that Peyer's reflex diarrhoea, which he derives from disorders of the prostate (Peyer, 1893), is nothing else than this diarrhoea of anxiety neurosis. The illusion of a reflex relationship is created because the same factors come into play in the aetiology of anxiety neurosis as are at work in the setting up of such affections of the prostate and similar disorders.

The behaviour of the gastro-intestinal tract in anxiety neurosis presents a sharp contrast to the influence of neurasthenia on those functions. Mixed cases often show the familiar 'alternation between diarrhoea and constipation'. Analogous to this diarrhoea is the need to urinate that occurs in anxiety neurosis.

(9) The *paraesthesias* which may accompany attacks of vertigo or anxiety are interesting because they, like the sensations of the hysterical aura, become associated in a definite sequence; although I find that these associations, in contrast to the hysterical ones, are atypical and changing. A further similarity to hysteria is provided by the fact that in anxiety neurosis a kind of *conversion*¹ takes place on to bodily sensations, which may easily be overlooked - for instance, on to rheumatic muscles. A whole number of what are known as rheumatic individuals who, moreover, can be shown to *be* rheumatic - are in reality suffering from anxiety neurosis. Along with this increase of sensitivity to pain, I have also observed in a number of cases of anxiety neurosis a tendency to *hallucinations*; and these could not be interpreted as hysterical.

(10) Several of the symptoms I have mentioned, which accompany or take the place of an anxiety attack, also appear in a chronic form. In that case they are still less easy to recognize, since the anxious sensation which goes with them is less clear than in an anxiety attack. This is especially true of diarrhoea, vertigo and paraesthesias. Just as an attack of vertigo can be replaced by a fainting fit, so chronic vertigo can be replaced by a constant feeling of great feebleness, lassitude and so on.

II

INCIDENCE AND AETIOLOGY OF ANXIETY NEUROSIS

In some cases of anxiety neurosis no aetiology at all is to be discovered. It is worth noting that in such cases there is seldom any difficulty in establishing evidence of a grave hereditary taint.

But where there are grounds for regarding the neurosis as an *acquired* one, careful enquiry directed to that end reveals that a set of noxae and influences from *sexual life* are the operative aetiological factors. These appear at first sight to be of a varied nature, but they soon disclose the common character which explains why they have a similar effect on the nervous system. Further, they are present either alone or together with other noxae of a 'stock' kind, to which we may ascribe a contributory effect. This sexual aetiology of anxiety neurosis can be demonstrated with such overwhelming frequency that I venture, *for the purpose of this short paper*, to disregard those cases where the aetiology is doubtful or different.

In order that the aetiological conditions under which anxiety neurosis makes its appearance may be presented with greater accuracy, it will be advisable to consider males and females separately. In females - disregarding for the moment their innate disposition - anxiety neurosis occurs in the following cases:

(a) As *virginal anxiety* or *anxiety in adolescents*. A number of unambiguous observations have shown me that anxiety neurosis can be produced in girls who are approaching maturity by their first encounter with the problem of sex, by any more or less sudden revelation of what had till then been hidden - for instance, by witnessing the sexual act, or being told or reading about these things. Such an anxiety neurosis is combined with hysteria in an almost typical fashion.

(b) As *anxiety in the newly married*. Young married women who have remained anaesthetic during their first cohabitations not seldom fall ill of an anxiety neurosis, which disappears once more as soon as the anaesthesia gives place to normal sensitivity. Since most young wives remain healthy where there is initial anaesthesia of this kind, it follows that, in order that this kind of anxiety shall emerge, other determinants are required; and these I will mention later.

(c) As anxiety in women whose husbands suffer from ejaculatio praecox or from markedly impaired potency; and (d) whose husbands practise coitus interruptus or reservatus. These cases belong together, for on analysing a great number of instances it is easy to convince oneself that they depend simply on whether the woman obtains satisfaction in coitus or not. If not, the condition for the genesis of an anxiety neurosis is given. On the other hand, she is saved from the neurosis if the husband who is affected with ejaculatio praecox is able immediately to repeat coitus with better success. Coitus reservatus *by means of condoms* is not injurious to the woman, provided she is very quickly excitable and the husband very potent; otherwise, this kind of preventive intercourse is no less injurious than the others. Coitus interruptus is nearly always a noxa. But for the wife it is only so if the husband practises it regardlessly - that is to say, if he breaks off intercourse as soon as *he* is near emission, without troubling himself about the course of the excitation in *her*. If, on the other hand, the husband waits for his wife's satisfaction, the coitus amounts to a normal one for *her*; but *he* will fall ill of an anxiety neurosis. I have collected and analysed a large number of observations, on which these assertions are based.

(e) Anxiety neurosis also occurs as anxiety in *widows* and intentionally *abstinent women*, not seldom in a typical combination with obsessional ideas; and

(f) As anxiety in the *climacteric* during the last major increase of sexual need.

Cases (c) (d) and (e) comprise the conditions under which anxiety neurosis in the female sex arises most frequently and most readily, independently of hereditary disposition. It is in reference to these cases of anxiety neurosis - these curable acquired cases - that I shall try to show that the sexual noxae discovered in them are really the aetiological factor of the neurosis.

Before doing so, however, I will discuss the sexual determinants of anxiety neurosis in *men*. I propose to distinguish the following groups, all of which have their analogies in women:

(a) Anxiety of intentionally *abstinent* men, which is frequently combined with symptoms of *defence* (obsessional ideas, hysteria). The motives which are responsible for intentional abstinence imply that a number of people with a hereditary disposition, eccentrics, etc., enter into this category.

(b) Anxiety in men in a state of *unconsummated excitation* (e.g. during the period of engagement before marriage), or in those who (from fear of the consequences of sexual intercourse) content themselves with touching or looking at women. This group of determinants - which, incidentally, can be applied unaltered to the other sex (during engagements or relations in which sexual intercourse is avoided) - provides the purest cases of the neurosis.

(c) Anxiety in men who practise coitus interruptus. As has been said, coitus interruptus is injurious to the *woman* if it is practised without regard to her satisfaction; but it is injurious to the *man* if, in order to obtain satisfaction for her, he directs coitus voluntarily and postpones emission. In this way it becomes intelligible that when a married couple practise coitus interruptus, it is, as a rule, only *one* partner who falls ill. Moreover, in men coitus interruptus only rarely produces a pure anxiety neurosis; it usually produces a mixture of anxiety neurosis and neurasthenia.

(d) Anxiety in *senescent* men. There are men who have a climacteric like women, and who produce an anxiety neurosis at the time of their decreasing potency and increasing libido.

Finally, I must add two other cases which apply to both sexes:

(α) People who, as a result of practising masturbation, have become neurasthenics, fall victims to anxiety neurosis as soon as they give up their form of sexual satisfaction. Such people have made themselves particularly incapable of tolerating abstinence.

I may note here, as being important for an understanding of anxiety neurosis, that any pronounced development of that affection only occurs among men who have remained potent and women who are not anaesthetic. Among neurotics whose potency has already been severely damaged by masturbation, the anxiety neurosis resulting from abstinence is very slight and is mostly restricted to hypochondria and mild chronic vertigo. The majority of women, indeed, are to be regarded as 'potent'; a really impotent - i.e. a really anaesthetic - woman is in a similar way little susceptible to anxiety neurosis, and she tolerates the noxae I have described remarkably well.

How far, in addition to this, we are justified in postulating any constant relation between particular aetiological factors and particular symptoms in the complex of anxiety neurosis, I should not like to discuss as yet in this paper.

(β) The last of the aetiological conditions I have to bring forward appears at first sight not to be of a sexual nature at all. Anxiety neurosis also arises - and in both sexes - as a result of the factor of overwork or exhausting exertion - as, for instance, after night-watching, sick-nursing, or even after severe illness.

The main objection to my postulate of a sexual aetiology for anxiety neurosis will probably be to the following effect. Abnormal conditions in sexual life of the kind I have described are found so extremely frequently that they are bound to be forthcoming wherever one looks for them. Their presence in the cases of anxiety neurosis which I have enumerated does not, therefore, prove that we have unearthed in them the aetiology of the neurosis. Moreover, the number of people who practise coitus interruptus and the like is incomparably larger than the number who are afflicted with anxiety neurosis, and the great majority of the former tolerate this noxa very well.

To this I must reply in the first place that, considering the admittedly enormous frequency of the neuroses and especially of anxiety neurosis, it would certainly not be right to expect to find an aetiological factor for them that is of *rare* occurrence; in the second place, that a postulate of pathology is in fact satisfied, if in an aetiological investigation it can be shown that the *presence* of an aetiological factor is more frequent than its effects, since, in order for these latter to occur, other conditions may have to exist in addition (such as disposition, summation of specific aetiological elements, or reinforcement by other stock noxae); and further, that a detailed dissection of suitable cases of anxiety neurosis proves beyond question the importance of the sexual factor. I will confine myself here, however, to the single aetiological factor of coitus interruptus and to bringing out certain observations which confirm it.

(1) So long as an anxiety neurosis in young married women is not yet established, but only appears in bouts and disappears again spontaneously, it is possible to demonstrate that each such bout of the neurosis is traceable to a coitus which was deficient in satisfaction. Two days after this experience - or, in the case of people with little resistance, the day after - the attack of anxiety or vertigo regularly appears, bringing in its train other symptoms of the neurosis. All this vanishes once more, provided that marital intercourse is comparatively rare. A chance absence of the husband from home, or a holiday in the mountains which necessitates a separation of the couple, has a good effect. The gynaecological treatment which is usually resorted to in the first instance is beneficial because, while it lasts, marital intercourse is stopped. Curiously enough the success of local treatment is only transitory: the neurosis sets in again in the mountains, as soon as the husband begins his holiday too; and so on. If, as a physician who understands this aetiology, one arranges, in a case in which the neurosis has not yet been established, for coitus interruptus to be replaced by normal intercourse, one obtains a *therapeutic* proof of the assertion I have made. The anxiety is removed, and - unless there is fresh cause for it of the same sort - it does not return.

(2) In the anamneses of many cases of anxiety neurosis we find, both in men and women, a striking oscillation in the intensity of its manifestations, and, indeed, in the coming and going of the whole condition. One year, they will tell you, was almost entirely good, but the next one was dreadful; on one occasion the improvement seemed to be due to a particular treatment, which, however, turned out to be quite useless at the next attack; and so on. If we enquire into the number and sequence of the children and compare this record of the marriage with the peculiar history of the neurosis, we arrive at the simple solution that the periods of improvement or good health coincided with the wife's pregnancies, during which, of course, the need for preventive intercourse was no longer present. The husband benefited by the treatment after which he found his wife pregnant - whether he received it from Pastor Kneipp or at a hydropathic establishment.

(3) The anamnesis of patients often discloses that the symptoms of anxiety neurosis have at some definite time succeeded the symptoms of some other neurosis - neurasthenia, perhaps - and have taken their place. In these instances it can quite regularly be shown that, shortly before this change of the picture, a corresponding change has occurred in the form of the sexual noxa.

Observations of this sort, which can be multiplied at will, positively thrust a sexual aetiology on the doctor for a certain category of cases. And other cases, which would otherwise remain unintelligible, can at least be understood and classified without inconsistency by employing that aetiology as a key. I have in mind those very numerous cases in which, it is true, everything is present that has been found in the previous category - on the one hand the manifestations of anxiety neurosis, and on the other the specific factor of coitus interruptus - but in which something else as well intrudes itself: namely, a long interval between the presumed aetiology and its effects, and also perhaps aetiological factors that are not of a sexual nature. Take, for instance, a man who, on receiving news of his father's death, had a heart attack and from that moment fell a victim to an anxiety neurosis. The case is not comprehensible, for, till then, the man was not neurotic. The death of his father, who was well advanced in years, did not take place under in any way special circumstances, and it will be admitted that the normal and expected decease of an aged father is not one of those experiences which usually cause a healthy adult to fall ill. Perhaps the aetiological analysis will become clearer if I add that this man had been practising coitus interruptus for eleven years, with due consideration for his wife's satisfaction. The clinical symptoms are, at least, exactly the same as those which appear in other people after only a short sexual noxa of the same kind, and without the interpolation of any other trauma. A similar assessment must be made of the case of a woman whose anxiety neurosis broke out after the loss of her child, or of the student whose preparatory studies for his final examination were interfered with by an anxiety neurosis. I think that in these instances, too, the effect is not explained by the ostensible aetiology. One is not necessarily 'overworked' by study, and a healthy mother as a rule reacts only with normal grief to the loss of a child. Above all, however, I should have expected the student, as a result of his overwork, to acquire cephalasthenia, and the mother, as a result of her bereavement, hysteria. That both should have been overtaken by anxiety neurosis leads me to attach importance to the fact that the mother had been living for eight years in conditions of marital coitus interruptus, and that the student had for three years had an ardent love affair with a 'respectable' girl whom he had to avoid making pregnant.

These considerations lead us to the conclusion that the specific sexual noxa of coitus interruptus, even when it is not able on its own account to provoke an anxiety neurosis in the subject, does at least *provoke* him to acquire it. The anxiety neurosis breaks out as soon as there is added to the latent effect of the specific factor the effect of another, stock noxa. The latter can act in the sense of the specific factor quantitatively but cannot replace it qualitatively. The specific factor always remains decisive for the *form* taken by the neurosis. I hope to be able to prove this assertion concerning the aetiology of the neuroses more comprehensively too.

In addition, these latter remarks contain an assumption which is not in itself improbable, to the effect that a sexual noxa like coitus interruptus comes into force through summation. A shorter or longer time is needed - depending on the individual's disposition and any other inherited weaknesses of his nervous system - before the effect of this summation becomes visible. Those individuals who apparently tolerate coitus interruptus without harm, in fact become disposed by it to the disorders of anxiety neurosis, and these may break out at some time or other, either spontaneously or after a stock trauma which would not ordinarily suffice for this; just as, by the path of summation, a chronic alcoholic will in the end develop a cirrhosis or some other illness, or will, under the influence of a fever, fall a victim to delirium.

III

FIRST STEPS TOWARD A THEORY OF ANXIETY NEUROSIS

The following theoretical discussion can only claim to have the value of a first, groping attempt; criticism of it ought not to affect an acceptance of the *facts* which have been brought forward above. Moreover, an assessment of this 'theory of anxiety neurosis' is made the more difficult from being only a fragment of a more comprehensive account of the neuroses.

What we have so far said about anxiety neurosis already provides a few starting points for gaining an insight into the mechanism of this neurosis. In the first place there was our suspicion that we had to do with an accumulation of excitation; and then there was the extremely important fact that the anxiety which underlies the clinical symptoms of the neurosis can be traced to *no psychical origin*. Such an origin would exist, for instance, if it was found that the anxiety neurosis was based on a single or repeated justifiable fright, and that that fright had since provided the source for the subject's readiness for anxiety. But this is not so. Hysteria or a traumatic neurosis can be acquired from a single fright, but never anxiety neurosis. Since coitus interruptus takes such a prominent place among the causes of anxiety neurosis, I thought at first that the source of the continuous anxiety might lie in the fear, recurring every time the sexual act was performed, that the technique might go wrong and conception consequently take place. But I have found that this state of feeling, either in the man or the woman, during coitus interruptus has no influence on the generation of anxiety neurosis, that women who are basically indifferent about the consequence of a possible conception are just as liable to the neurosis as those who shudder at the possibility, and that everything depends simply on which partner has forfeited satisfaction in this sexual technique.

A further point of departure is furnished by the observation, not so far mentioned, that in whole sets of cases anxiety neurosis is accompanied by a most noticeable decrease of sexual libido or *psychical desire*, so that on being told that their complaint results from 'insufficient satisfaction', patients regularly reply that that is impossible, for precisely now all sexual need has become extinguished in them. From all these indications - that we have to do with an accumulation of excitation; that the anxiety which probably corresponds to this accumulated excitation is of somatic origin, so that what is being accumulated is a *somatic* excitation; and, further, that this somatic excitation is of a sexual nature and that a decrease of *psychical* participation in the sexual processes goes along with it - all these indications, I say, incline us to expect that *the mechanism of anxiety is to be looked for in a deflection of somatic excitation from the psychical sphere, and in a consequent abnormal employment of that excitation*.

This concept of the mechanism of anxiety neurosis can be made clearer if one accepts the following view of the sexual process, which applies, in the first instance, to men. In the sexually mature male organism somatic sexual excitation is produced probably continuously - and periodically becomes a stimulus to the psyche. In order to make our ideas on this point firmer, I will add by way of interpolation that this somatic excitation is manifested as a pressure on the walls of the seminal vesicles, which are lined with nerve endings; thus this visceral excitation will develop continuously, but it will have to reach a certain height before it is able to overcome the resistance of the intervening path of conduction to the cerebral cortex and express itself as a psychical stimulus. When this has happened, however, the group of sexual ideas which is present in the psyche becomes supplied with energy and there comes into being the psychical state of libidinal tension which brings with it an urge to remove that tension. A psychical unloading of this kind is only possible by means of what I shall call *specific* or *adequate* action. This adequate action consists, for the male sexual instinct, in a complicated spinal reflex act which brings about the unloading of the nerve-endings, and in all the psychical preparations which have to be made in order to set off that reflex. Anything other than the adequate action would be fruitless, for once the somatic sexual excitation has reached threshold value it is turned continuously into psychical excitation, and something must positively take place which will free the nerve endings from the load of pressure on them - which will, accordingly, remove the whole of the existing somatic excitation and allow the subcortical path of conduction to re-establish its resistance.

I shall refrain from describing more complicated instances of the sexual process in a similar way. I will only state that in essentials this formula is applicable to women as well, in spite of the confusion introduced into the problem by all the artificial retarding and stunting of the female sexual instinct. In women too we must postulate a somatic sexual excitation and a state in which this excitation becomes a psychical stimulus - libido - and provokes the urge to the specific action to which voluptuous feeling is attached. Where women are concerned, however, we are not in a position to say what the process analogous to the relaxation of tension of the seminal vesicles may be.

We can include within the framework of this description of the sexual process not only the aetiology of anxiety neurosis but that of genuine neurasthenia. Neurasthenia develops whenever the adequate unloading (the adequate action) is replaced by a less adequate one - thus, when normal coition, carried out in the most favourable conditions, is replaced by masturbation or spontaneous emission. Anxiety neurosis, on the other hand, is the product of all those factors which prevent the somatic sexual excitation from being worked over psychically. The manifestations of anxiety neurosis appear when the somatic excitation which has been deflected from the psyche is expended subcortically in totally inadequate reactions.

I will now attempt to discover whether the aetiological conditions for anxiety neurosis which I set out above exhibit the common character that I have just attributed to them. The first aetiological factor I postulated for men was intentional abstinence. Abstinence consists in the withholding of the specific action which ordinarily follows upon libido. Such withholding may have two consequences. In the first place, the somatic excitation accumulates; it is then deflected into other paths, which hold out greater promise of discharge than does the path through the psyche. Thus the libido will in the end sink, and the excitation will manifest itself subcortically as anxiety. In the second place, if the libido is not diminished, or if the somatic excitation is expended, by a short cut, in emissions, or if, in consequence of being forced back, the excitation really ceases, then all kinds of things other than an anxiety neurosis will ensue. Abstinence, then, leads to anxiety neurosis in the manner described above. But it is also the operative agent in my second aetiological group, that of unconsummated excitation. My third group, that of coitus reservatus with consideration for the woman, operates by disturbing the man's psychical preparedness for the sexual process, in that it introduces alongside of the task of mastering the sexual affect another psychical task, one of a deflecting sort. In consequence of this psychical deflection, once more, libido gradually disappears, and the further course of things is then the same as in the case of abstinence. Anxiety in senescence (the male climacteric) requires another explanation. Here there is no diminution of libido; but, as in the female climacteric, so great an increase occurs in the production of somatic excitation that the psyche proves relatively insufficient to master it.

The aetiological conditions applying to women can be brought into the framework of my scheme with no greater difficulties than in the case of men. Virginal anxiety is a particularly clear example. For here the groups of ideas to which the somatic sexual excitation should become attached are not yet enough developed. In the newly-married woman who is anaesthetic, anxiety only appears if the first cohabitations arouse a sufficient amount of somatic excitation. When the local indications of such excitement (spontaneous sensations of stimulation, desire to micturate and so on) are lacking, anxiety is also absent. The case of ejaculatio praecox and of coitus interruptus can be explained on the same lines as in men, namely that the libidinal desire for the psychically unsatisfying act gradually disappears, while the excitation which has been aroused during the act is expended subcortically. The *alienation* between the somatic and the psychical sphere is established more readily and is more difficult to remove in women than in men. The cases of widowhood and of voluntary abstinence, and also that of the climacteric, are dealt with in the same way in both sexes; but where abstinence is concerned there is in the case of women no doubt the further matter of intentional repression of the sexual circle of ideas, to which an abstinent woman, in her struggle against temptation, must often make up her mind. The horror which, at the time of the menopause, an ageing woman feels at her unduly increased libido may act in a similar sense.

The two last aetiological conditions on our list seem to fall into place without difficulty. The tendency to anxiety in masturbators who have become neurasthenic is explained by the fact that it is very easy for them to pass into a state of 'abstinence' after they have been accustomed for so long to discharging even the smallest quantity of somatic excitation, faulty though that discharge is. Finally, the last case, - the generation of anxiety neurosis through severe illness, overwork, exhausting sick-nursing, etc., - finds an easy interpretation when brought into relation with the effects of coitus interruptus. Here the psyche, on account of its deflection, would seem to be no longer capable of mastering the somatic excitation, a task on which, as we know, it is continuously engaged. We are aware to what a low level libido can sink under these conditions; and we have here a good example of a neurosis which, although it exhibits *no sexual aetiology, nevertheless exhibits a sexual mechanism*.

The view here developed depicts the symptoms of anxiety neurosis as being in a sense *surrogates* of the omitted specific action following on sexual excitation. In further support of this view, I may point out that in normal copulation too the excitation expends itself, among other things, in accelerated breathing, palpitation, sweating, congestion, and so on. In the corresponding anxiety attacks of our neurosis we have before us the dyspnoea, palpitations, etc. of copulation in an isolated and exaggerated form.

A further question may be asked. Why, under such conditions of psychical insufficiency in mastering sexual excitation, does the nervous system find itself in the peculiar affective state of anxiety? An answer may be suggested as follows. The psyche finds itself in the *affect* of anxiety if it feels unable to deal by appropriate reaction with a task (a danger) *approaching from the outside*; it finds itself in the *neurosis* of anxiety if it notices that it is unable to even out the (sexual) excitation originating *from within* - that is to say, *it behaves as though it were projecting that excitation outwards*. The affect and its corresponding neurosis are firmly related to each other. The first is a reaction to an exogenous excitation, the second a reaction to the analogous endogenous one. The affect is a state which passes rapidly, the neurosis is a chronic one; because, while exogenous excitation operates with a single impact, the endogenous excitation operates as a constant force. *In the neurosis, the nervous system is reacting against a source of excitation which is internal, whereas in the corresponding affect it is reacting against an analogous source of excitation which is external.*

IV

RELATION TO OTHER NEUROSES

There are still a few words to be said about the relations of anxiety neurosis to the other neuroses as regards their onset and their internal connections.

The purest cases of anxiety neurosis are usually the most marked. They are found in sexually potent youthful individuals, with an undivided aetiology, and an illness that is not of too long standing.

More often, however, symptoms of anxiety occur at the same time as, and in combination with, symptoms of neurasthenia, hysteria, obsessions or melancholia. If we were to allow ourselves to be restrained by a clinical intermixture like this from acknowledging anxiety neurosis as an independent entity, we ought, logically, also to abandon once more the separation which has been so laboriously achieved between hysteria and neurasthenia.

For the purposes of analysing 'mixed neuroses' I can state this important truth: *Wherever a mixed neurosis is present, it will be possible to discover an intermixture of several specific aetiologies.*

A multiplicity of aetiological factors such as this, which determine a mixed neurosis, may occur purely fortuitously. For instance, a fresh noxa may add its effects to those of an already existing one. Thus, a woman who has always been hysterical may begin at a certain point in her marriage to experience coitus reservatus; she will then acquire an anxiety neurosis in addition to her hysteria. Or again, a man who has hitherto masturbated and has become neurasthenic, may get engaged and become sexually excited by his fiancée; his neurasthenia will now be joined by a new anxiety neurosis.

In other cases the multiplicity of aetiological factors is by no means fortuitous: one of the factors has brought the other into operation. For example, a woman with whom her husband practises coitus reservatus without regard to her satisfaction may find herself compelled to masturbate in order to put an end to the distressing excitation that follows such an act; as a result, she will produce, not an anxiety neurosis pure and simple, but an anxiety neurosis accompanied by symptoms of neurasthenia. Another woman suffering from the same noxa may have to fight against lascivious images against which she tries to defend herself; and in this way she will, through the coitus interruptus, acquire obsessions as well as an anxiety neurosis. Finally, as a result of coitus interruptus, a third woman may lose her affection for her husband and feel an attraction for another man, which she carefully keeps secret; in consequence, she will exhibit a mixture of anxiety neurosis and hysteria.

In a third category of mixed neuroses the interconnection between the symptoms is still more intimate, in that the same aetiological determinant regularly and simultaneously provokes both neuroses. Thus, for instance, the sudden sexual enlightenment, which we have found present in virginal anxiety, always gives rise to hysteria as well; by far the majority of cases of intentional abstinence become linked from the beginning with true obsessional ideas; coitus interruptus in men never seems to me to be able to provoke a pure anxiety neurosis, but always a mixture of it with neurasthenia.

From these considerations it appears that we must further distinguish the aetiological conditions for the *onset* of the neuroses from their specific aetiological factors. The former - for example, coitus interruptus, masturbation or abstinence - are still ambiguous, and each of them can produce different neuroses. Only the aetiological factors which can be picked out in them, such as *inadequate disburdening, psychical insufficiency or defence accompanied by substitution*, have an unambiguous and specific relation to the aetiology of the individual major neuroses.

As regards its intimate nature, anxiety neurosis presents the most interesting agreements with, and differences from, the other major neuroses, in particular neurasthenia and hysteria. It shares with neurasthenia one main characteristic - namely that the source of excitation, the precipitating cause of the disturbance, lies in the somatic field instead of the psychical one, as is the case in hysteria and obsessional neurosis. In other respects we rather find a kind of antithesis between the symptoms of anxiety neurosis and of neurasthenia, which might be brought out by such labels as 'accumulation of excitation' and 'impoverishment of excitation'. This antithesis does not prevent the two neuroses from being intermixed with each other; but it nevertheless shows itself in the fact that the most extreme forms of each are in both cases also the purest.

The symptomatology of hysteria and anxiety neurosis show many points in common which have not yet been sufficiently considered. The appearance of symptoms either in a chronic form or in attacks, the paraesthesias, grouped like *aurae*, the hyperaesthesias and pressure-points which are found in certain surrogates of an anxiety attack (in dyspnoea and heart-attacks), the intensification, through conversion, of pains which perhaps have an organic justification - these and other features which the two illnesses have in common even allow of a suspicion that not a little of what is attributed to hysteria might with more justice be put to the account of anxiety neurosis. If one goes into the mechanism of the two neuroses, so far as it has been possible to discover it hitherto, aspects come to light which suggest that anxiety neurosis is actually the somatic counterpart to hysteria. In the latter just as in the former there is an accumulation of excitation (which is perhaps the basis for the similarity between their symptoms we have mentioned). In the latter just as in the former we find a *psychical insufficiency, as a consequence of which abnormal somatic processes arise*. In the latter just as in the former, too, instead of a psychical working-over of the excitation, a deflection of it occurs into the somatic field; the difference is merely that in anxiety neurosis the excitation, in whose displacement the neurosis expresses itself, is purely somatic (somatic sexual excitation), whereas in hysteria it is psychical (provoked by conflict). Thus it is not to be wondered at that hysteria and anxiety neurosis regularly combine with each other, as is seen in 'virginal anxiety' or in 'sexual hysteria', and that hysteria simply borrows a number of its symptoms from anxiety neurosis, and so on. These intimate relations which anxiety neurosis has with hysteria provide a fresh argument, moreover, for insisting on the detachment of anxiety neurosis from neurasthenia; for if this detachment is not granted, we shall also be unable any longer to maintain the distinction which has been acquired with so much labour and which is so indispensable for the theory of the neuroses, between neurasthenia and hysteria.

A REPLY TO CRITICISMS OF MY PAPER ON ANXIETY NEUROSIS

(1895)

Intentionally left blank

A REPLY TO CRITICISMS OF MY PAPER ON ANXIETY NEUROSIS

In the second number of Mendel's *Neurologisches Zentralblatt* for 1895, I published a short paper in which I ventured an attempt to detach a number of nervous states from neurasthenia and to establish them as an independent entity under the name of 'anxiety neurosis'.¹ I was led to do so by the presence of a constant conjunction of certain clinical features with certain aetiological ones - a thing which, in general, should permit us to make a separation of this kind. I found - and in this Hecker (1893) had anticipated me - that the neurotic symptoms in question could all be classed together as constituting expressions of anxiety; and, from my study of the aetiology of the neuroses, I was able to add that these portions of the complex of the 'anxiety neurosis' exhibit special aetiological preconditions which are almost the opposite of the aetiology of neurasthenia. My observations had shown me that in the aetiology of the neuroses (at all events of *acquired* cases and *acquirable* forms) sexual factors play a predominant part and one which has been given far too little weight; so that a statement such as that 'the aetiology of the neuroses lies in sexuality', with all its unavoidable incorrectness *per excessum et defectum*, nevertheless comes nearer to the truth than do the other doctrines, which hold the field at the present time. A further assertion which my observations forced me to make was to the effect that the various sexual noxae are not to be found in the aetiology of every neurosis indifferently, but that unmistakable special relationships hold between particular noxae and particular neuroses. Thus I could assume that I had discovered the *specific* causes of the various neuroses. I then sought to formulate shortly the special character of the sexual noxae which constitute the aetiology of anxiety neurosis, and, on the basis of my view of the sexual process (p. 108), I arrived at the proposition: anxiety neurosis is created by everything which keeps somatic sexual tension away from the psychical sphere, which interferes with its being worked over psychically. If we go back to the concrete circumstances in which this factor becomes operative, we are led to assert that abstinence, whether voluntary or involuntary, sexual intercourse with incomplete satisfaction, coitus interruptus, deflection of psychical interest from sexuality, and similar things, are the specific aetiological factors of the states to which I have given the name of anxiety neurosis.

¹ 'On the Grounds for Detaching a Particular Syndrome from Neurasthenia under the Description "Anxiety Neurosis"' (1895b).

When I published the paper I have mentioned, I was under no illusion as to its power to carry conviction. In the first place, I was aware that the account I had given was only a brief and incomplete one and even in places hard to understand - just enough, perhaps, to arouse the reader's expectations. Then, too, I had scarcely brought forward any examples and given no figures. Nor had I touched on the technique of collecting anamneses or done anything to prevent misunderstandings. I had not given consideration to any but the most obvious objections; and, as regards the theory itself, I had laid stress only on its main proposition and not on its qualifications. Accordingly, each reader was in fact at liberty to form his own opinion as to the binding force of the whole hypothesis. I could, moreover, reckon upon another difficulty in the way of its acceptance. I know very well that in putting forward my 'sexual aetiology' of the neuroses, I have brought up nothing new, and that undercurrents in medical literature taking these facts into account have never been absent. I know, too, that official academic medicine has in fact also been aware of them. But it has acted as if it knew nothing about the matter. It has made no use of its knowledge and has drawn no inferences from it. Such behaviour must have a deep-seated cause, originating perhaps in a kind of reluctance to look squarely at sexual matters or in a reaction against older attempts at an explanation, which are regarded as obsolete. At all events, one had to be prepared to meet with resistance in venturing upon an attempt to make something credible to other people which they could without any trouble have discovered for themselves.

In such circumstances it would perhaps be more expedient not to answer critical objections until I had myself expressed my views on this complicated subject in greater detail and had made them more intelligible. Nevertheless, I cannot resist the motives which prompt me to make an immediate answer to a criticism of my theory of anxiety neurosis which has appeared in recent days. I do so because its author, L. Löwenfeld of Munich, the author of *Pathologie und Therapie der Neurasthenia*, is a man whose judgement undoubtedly carries great weight with the medical public; because of a mistaken view which Löwenfeld's account imputes to me; and finally because I wish to combat at the very start the impression that my theory can be refuted quite so easily by the first objections that come to hand.

With an unerring eye Löwenfeld (1895) detects the essential feature of my paper - namely, my assertion that anxiety-symptoms have a specific and uniform aetiology of a sexual nature. If this cannot be established as a fact, then the main reason for detaching an independent anxiety neurosis from neurasthenia disappears as well. There remains, it is true, one difficulty to which I called attention - the fact that anxiety-symptoms also have such very unmistakable connections with hysteria, so that a decision on Löwenfeld's lines would prejudice the separation between hysteria and neurasthenia. This difficulty, however, is met by a recourse to heredity as the common cause of all these neuroses (a view which I will go into later).

What arguments, then, does Löwenfeld use to support his objection to my theory?

(1) I emphasized as a point essential to an understanding of anxiety neurosis that the anxiety appearing in it does not admit of a psychical derivation - that is to say that the preparedness for anxiety, which constitutes the nucleus of the neurosis, cannot be acquired by a single or repeated affect of psychically justified fright. Fright, I maintained, might result in hysteria or a traumatic neurosis, but not in an anxiety neurosis. This denial, it is easy to see, is nothing else than the counterpart to my contention, on the positive side, that the anxiety appearing in my neurosis corresponds to a somatic sexual tension which has been deflected from the psychical field - a tension which would otherwise have made itself felt as libido.

Against this, Löwenfeld insists on the fact that in a number of cases 'states of anxiety appear immediately or shortly after a psychical shock (fright alone, or accidents which were accompanied by fright), and in such situations there are sometimes circumstances which make the simultaneous operation of sexual noxae of the kind mentioned extremely improbable.' He gives, shortly, as a particularly pregnant example, one clinical observation (to serve instead of many). This example concerns a woman of thirty, with a hereditary taint, who had been married for four years and who had had a first, difficult, confinement a year before. A few weeks after this event her husband had an attack of illness which frightened her, and in her agitation she ran about the cold room in her chemise. From that time on she was ill. First she had states of anxiety and palpitations in the evening, then came attacks of convulsive trembling, and after that phobias, and so on. It was the picture of a fully-developed anxiety neurosis. 'Here,' concludes Löwenfeld, 'the anxiety states are obviously of psychical origin, brought about by the single fright.'

I do not doubt that my respected critic can produce many similar cases. I myself can supply a long list of analogous examples. Anyone who has not seen such cases - and they are extremely common - of an outbreak of anxiety neurosis after a psychical shock, ought not to regard himself as qualified to take part in discussions about anxiety neurosis. I will only remark in this connection that neither fright nor anxious expectation need always be found in the aetiology of such cases; any other emotion will do as well. If I hastily recall a few cases from my memory, I think of a man of forty-five who had his first attack of anxiety (with cardiac collapse) at the news of the death of his father, who was an old man; from that time on he developed a complete and typical anxiety neurosis with agoraphobia. Again, I think of a young man who was overtaken by the same neurosis on account of his agitation about the disagreements between his young wife and his mother and who had a fresh onset of agoraphobia after every domestic quarrel. Then, there was a student, something of an idler, who produced his first anxiety attacks during a period in which, under the spur of his father's displeasure, he was working hard for an examination. I recall, too, a woman, herself childless, who fell ill as a result of anxiety about the health of a small niece. And other similar instances. About the facts themselves, which Löwenfeld uses against me, there is not the slightest doubt.

But there is doubt about their interpretation. Are we to accept the *post hoc ergo propter hoc* conclusion straight away and spare ourselves any critical consideration of the raw material? There are examples enough in which the final, releasing cause has not, in the face of critical analysis, maintained its position as the *causa efficiens*. One has only to think, for instance, of the relationship between trauma and gout. The role of a trauma in provoking an attack of gout in the injured limb is probably no different from the role it plays in the aetiology of tabes and general paralysis of the insane; only in the case of gout it is clear to the meanest capacity that it is absurd to suppose that the trauma has 'caused' the gout instead of having merely provoked it. It is bound to make us thoughtful when we come across aetiological factors of this sort - 'stock' factors, as I should like to call them - in the aetiology of the most varied forms of illness. Emotion, fright, is also a stock factor of this kind. Fright can provoke chorea, apoplexy, paralysis agitans and many other things just as well as it can provoke anxiety neurosis. I must not go on to argue, of course, that, because of their ubiquity, the stock causes do not satisfy our requirements and that there must be specific causes as well; to do so would be to beg the question in favour of the proposition I want to prove. But I am justified in drawing the following conclusion: if the same specific cause can be shown to exist in the aetiology of all, or the great majority, of cases of anxiety neurosis, our view of the matter need not be shaken by the fact that the illness does not break out until one or other stock factor, such as emotion, has come into operation.

So it was with my cases of anxiety neurosis. Let us take the man who, after receiving the news of his father's death, fell ill so inexplicably. (I add 'inexplicably' because the death was not unexpected and did not occur in unusual or shattering circumstances.) This man had carried out coitus interruptus for eleven years with his wife, whom he tried for the most part to satisfy. Again, the young man who was not equal to the quarrels between his wife and his mother, had practised withdrawal with his young wife from the first, in order to spare himself the burden of children. Then we have the student who acquired an anxiety neurosis from overwork, instead of the cerebral neurasthenia that was to be expected: he had maintained a relationship for three years with a girl whom it was not permissible for him to make pregnant. Again, there was the woman who, childless herself, was overtaken by an anxiety neurosis about a niece's illness: she was married to an impotent man and had never been sexually satisfied. And so on. Not all these cases are equally clear or equally good evidence for my thesis; but when I add them to the very considerable number of cases in which the aetiology shows nothing but the specific factor, they fit without contradiction into the theory I have put forward and they allow of an extension of our aetiological understanding beyond the boundaries hitherto in force.

If anyone wants to prove to me that in these remarks I have unduly neglected the significance of the stock aetiological factors, he must confront me with observations in which my specific factor is missing - that is, with cases in which anxiety neurosis has arisen after a psychical shock although the subject has (on the whole) led a *normal vita sexualis*. Let us see now whether Löwenfeld's case fulfils this condition. My respected opponent has evidently not been clear about this necessity in his own mind, otherwise he would not have left us so completely in the dark about his patient's *vita sexualis*. I will leave on one side the fact that this case of a lady of thirty is obviously complicated by a hysteria as to the psychical origin of which I have not the least doubt; and I naturally admit without raising any objection the presence of an anxiety neurosis alongside of this hysteria. But before I turn a case to account for or against the theory of the sexual aetiology of the neuroses, I must first have studied the patient's sexual behaviour more closely than Löwenfeld has done here. I should not be content to conclude that, because the time at which the lady received her psychical shock was shortly after a confinement, coitus interruptus could not have played a part during the previous year, and that therefore sexual noxae are ruled out. I know cases of women who were made pregnant every year, and who yet had anxiety neurosis, because - incredible as it may seem - all sexual relations were stopped after the first fertilizing coition, so that in spite of having many children they suffered from sexual privation through all these years. No doctor is ignorant of the fact that women conceive from men whose potency is very slight and who are not able to give them satisfaction. Finally (and this is a consideration which should be taken into account precisely by the upholders of a hereditary aetiology), there are plenty of women who are afflicted with congenital anxiety neurosis - that is to say, who inherit, or who develop without any demonstrable disturbance from outside, a *vita sexualis* which is the same as the one usually acquired through coitus interruptus and similar noxae. In a number of these women we are able to discover a hysterical illness in their youth, since which their *vita sexualis* has been disturbed and a deflection of sexual tension from the psychical sphere has been established. Women with this kind of sexuality are incapable of obtaining real satisfaction even from normal coitus, and they develop anxiety neurosis either spontaneously or after further operative factors have supervened. Which of all these elements were present in Löwenfeld's case? I do not know. But I repeat: this case is evidence against me only if the lady who responded to a single fright with an anxiety neurosis had before then enjoyed a normal *vita sexualis*.

It is impossible to pursue an aetiological investigation based on anamneses if we accept those anamneses as the patients present them, or are content with what they are willing to volunteer. If syphilidologists still depended on the statements of their patients for tracing back an initial infection of the genitals to sexual intercourse, they would be able to attribute an imposing number of chancres in allegedly virginal persons to catching a chill; and gynaecologists would have little difficulty in confirming the miracle of parthenogenesis among their unmarried lady clients. I hope that one day the idea will prevail that neuropathologists, too, in collecting the anamneses of major neuroses, may proceed upon aetiological prejudices of a similar kind.

(2) Löwenfeld says further that he has repeatedly seen anxiety states appear and disappear where a change in the subject's sexual life had certainly not taken place but where other factors were in play.

I, too, have made exactly the same observation, without, however, being misled by it. I myself have caused anxiety attacks to disappear by means of psychical treatment, improvement of the patient's general health, and so on; but I have naturally not concluded from this that what had caused the anxiety attack was a lack of treatment. Not that I should like to foist a conclusion of this sort upon Löwenfeld. My joking remark is only intended to show that the state of affairs may easily be complicated enough to render Löwenfeld's objection quite invalid. I have not found it difficult to reconcile the fact brought forward here with my assertion that anxiety neurosis has a specific aetiology. It will readily be granted that there are aetiological factors which, in order to exercise their effect, must operate with a certain intensity (or quantity) and over a certain period of time - which, that is to say, become *summated*. The effects of alcohol are a standard example of causation like this through summation. It follows that there must be a period of time in which the specific aetiology is at work but in which its effect is not yet manifest. During this time the subject is not ill as yet, but he is predisposed to a particular illness - in our case, to anxiety neurosis - and now the addition of a stock noxa will be able to set the neurosis off, just as would a further intensification of the operation of the specific noxa. The situation may also be expressed as follows: it is not enough for the specific noxa to be present; it must also reach a definite amount; and, in the process of reaching that limit, a quantity of specific noxa can be replaced by a quota of stock noxa. If the latter is removed once more, we find ourselves below a certain threshold and the clinical symptoms depart once more. The whole therapy of the neuroses rests upon the fact that the total load upon the nervous system, to which it has succumbed, can be brought below this threshold by influencing the aetiological mixture in a great variety of ways. From these circumstances we can draw no conclusion as to the existence or non-existence of a specific aetiology. These considerations are surely indisputable and assured. But anyone who does not think them sufficient may be influenced by the following argument. According to the views of Löwenfeld and very many others, the aetiology of anxiety states is to be found in heredity. Now heredity is certainly immune to alteration; thus if anxiety neurosis is curable by treatment, we should have to conclude according to Löwenfeld's argument that its aetiology *cannot* reside in heredity.

For the rest, I might have been spared having to defend myself against these two objections of Löwenfeld's, if my respected opponent had paid greater attention to my paper itself. In it, both these objections are anticipated and answered. I have only been able to repeat here what I said there; and I have even purposely analysed the same cases over again. Moreover the aetiological formulas on which I have just laid weight are contained in the text of my paper. I will repeat them once more. I maintain that *there exists a specific aetiological factor for anxiety neurosis which can be replaced in its operation by stock noxae in a QUANTITATIVE sense, but not in a QUALITATIVE one*; I furthermore maintain that *this specific factor determines above all the FORM of the neurosis; whether a neurotic illness occurs at all depends on the total load upon the nervous system (in proportion to its capacity to carry the load)*. As a rule the neuroses are *overdetermined*; that is to say, several factors operate together in their aetiology.

(3) I need not concern myself so much about refuting Löwenfeld's next comments, since on the one hand they damage my theory very little and on the other they raise difficulties whose existence I acknowledge. Löwenfeld writes: 'The Freudian theory is totally insufficient to explain the appearance or non-appearance of anxiety attacks in individual instances. If anxiety-states - i. e. the clinical symptoms of anxiety neurosis - occurred solely through a subcortical storing-up of somatic sexual excitation and an abnormal employment of it, then every person who is afflicted with anxiety-states ought, so long as no changes take place in his sexual life, to have an anxiety attack from time to time, just as an epileptic has his attack of *grand* and *petit mal*. But this, as everyday experience shows, is by no means so. The anxiety attacks happen in the great majority of instances only on definite occasions; if the patient avoids these occasions or is able to paralyse their influence by taking some precaution, he remains exempt from anxiety attacks, whether he is consistently given over to coitus interruptus or to abstinence, or whether he enjoys a normal sexual life.'

There is a great deal to be said about this. In the first place, Löwenfeld forces upon my theory an inference which it is not bound to accept. To suppose that in the storing-up of somatic sexual excitation the same thing must be happening as in the accumulation of the stimulus which leads to an epileptic convulsion, is to make a far too detailed hypothesis, and I have given no occasion for it; nor is it the only one that presents itself. I need only assume that the nervous system has the power to master a certain amount of somatic sexual excitation even where the latter is deflected from its aim, and that disturbances only occur when that quantum of excitation receives a sudden increment, and Löwenfeld's claim would be disposed of. I have not ventured to extend my theory in that direction, chiefly because I did not expect to find any solid points of support along that path. I should merely like to indicate that we ought not to think of the *production* of sexual tension independently of its *distribution*; that in normal sexual life this production, when it is stimulated by a sexual object, takes on a substantially different form from what it does in a state of psychological quiescence; and so on.

It must be admitted that the condition of affairs here is in all probability different from what prevails in the tendency to epileptic convulsions, and that it cannot yet be consistently derived from the theory of the accumulation of somatic sexual excitation.

Against Löwenfeld's further assertion - that anxiety-states only appear under certain conditions and fail to appear when those conditions are avoided, regardless of what the subject's *vita sexualis* may be - it must be pointed out that he clearly has in mind here only the anxiety of *phobias*, as, indeed, is shown by the examples attached to the passage I have quoted. He says nothing at all about the spontaneous anxiety attacks which take the form of vertigo, palpitation, dyspnoea, trembling, sweating, and so on. My theory, on the contrary, seems by no means unequal to explaining the emergence or non-emergence of these attacks of anxiety. For in a whole number of such cases of anxiety neurosis there does in fact appear to be a periodicity in the emergence of the states of anxiety, similar to what has been observed in epilepsy, except that in the latter the mechanism of the periodicity is more transparent. On closer examination we discover the presence, with great regularity, of an excitatory sexual process (that is, a process which is able to generate somatic sexual tension), and which, after the lapse of a definite and often constant interval of time, is followed by the anxiety attack. This role is played, in abstinent women, by menstrual excitation; it is played, too, by nocturnal pollutions, which also recur periodically. Above all, it is played by sexual intercourse itself (harmful from its being incomplete), which carries over its own periodicity to the effects it brings about, viz. to the anxiety attacks. If anxiety attacks occur which break through the usual periodicity, it is generally possible to trace them back to an incidental cause of rare and irregular occurrence - to a single sexual experience, something read or seen, and the like. The interval I have mentioned varies from a few hours to two days; it is the same as that which elapses in other people between the occurrence of the same causes and the onset of the well-known sexual migraine, which has well-established connections with the syndrome of anxiety neurosis.

Besides this, there are plenty of cases in which a single anxiety-state is provoked by the extra addition of a stock factor, by an excitement of some kind or other. The same holds good, therefore, for the aetiology of the individual anxiety attack as for the causation of the whole neurosis. It is not very strange that the anxiety of the phobias should obey different conditions; they have a more complicated structure than purely somatic anxiety attacks. In phobias the anxiety is linked to a definite ideational or perceptual content, and the arousal of this psychical content is the chief condition for the emergence of the anxiety. When this happens, anxiety is 'generated', just as for instance sexual tension is generated by the arousal of libidinal ideas. The connection of this process, however, with the theory of anxiety neurosis has not yet been elucidated.

I see no reason why I should try to hide the gaps and weaknesses in my theory. The main thing about the problem of the phobias seems to me to be that *when the vita sexualis is normal* - then the specific condition, a disturbance of sexual life in the sense of a deflection of the somatic from the psychical, is not fulfilled - *phobias do not appear at all*. However much else may be obscure about the mechanism of phobias, my theory can only be refuted when I have been shown phobias where sexual life is normal or even where there is a disturbance of it of a non-specific sort.

(4) I now pass on to a remark by my esteemed critic which I cannot leave uncontradicted. In my paper on anxiety neurosis I had written:

'In some cases of anxiety neurosis no aetiology at all is to be discovered. It is worth noting that in such cases there is seldom any difficulty in establishing evidence of a grave hereditary taint.

'But where there are grounds for regarding the neurosis as an *acquired* one, careful enquiry directed to that end reveals that a set of noxae and influences from *sexual life . . .*' Löwenfeld quotes this passage and adds the following gloss: 'From this it appears that Freud always regards a neurosis as "acquired" whenever incidental causes are to be found for it.'

If this meaning follows naturally from my text, then the latter gives a very distorted expression to my thoughts. Let me point out that in the preceding pages I have shown myself far stricter than Löwenfeld in my evaluation of incidental causes. If I were myself to elucidate the meaning of the passage I wrote I should add, after the subordinate clause 'But where there are grounds for regarding the neurosis as an *acquired* one . . .', the words '*because evidence (referred to in the previous sentence) of a hereditary taint is not forthcoming . . .*' What this means is that I hold the case to be an acquired one, since no heredity is to be discovered in it. In doing so I am behaving like everyone else, perhaps with the slight difference that others may declare the case to be determined by heredity even when there is no heredity, so that they overlook the whole category of acquired neuroses. But this difference runs in my favour. I admit, however, that I am myself to blame for this misunderstanding, on account of the way in which I expressed myself in the first sentence: 'no aetiology at all is to be discovered'. I shall certainly be taken to task from other directions as well and be told that I have created useless trouble for myself by searching for the specific causes of neuroses. Some will say that the true aetiology of anxiety neurosis, as of neuroses in general, is known: it is heredity. And two real causes cannot exist side by side. I have not, they will say, denied the aetiological role of heredity; but if so, all other aetiologies are merely incidental causes and equal to one another in value or want of value.

I do not share this view of the role of heredity; and since in my short paper on anxiety neurosis it is precisely to this theme that I have paid least attention, I will now try to make good some of what I have omitted in it and to remove the impression that in writing my paper I had not attended to all the relevant problems.

I think we can arrive at a picture of the probably very complicated aetiological situation which prevails in the pathology of the neuroses if we postulate the following concepts:

(a) *Precondition*, (b) *Specific Cause*, (c) *Concurrent Causes*, and, as a term which is not equivalent to the foregoing ones, (d) *Precipitating or Releasing Cause*.

In order to meet every possibility, let us assume that the aetiological factors we are concerned with are capable of a quantitative change - that is of increase or decrease.

If we accept the idea of an aetiological equation of several terms which must be satisfied if the effect is to take place, then we may characterize as the *precipitating* or releasing cause the one which makes its appearance last in the equation, so that it immediately precedes the emergence of the effect. It is this chronological factor alone which constitutes the essential nature of a precipitating cause. Any of the other causes, too, can in a particular case play the role of precipitating cause; and this role can change within the same aetiological combination.

The factors which may be described as *preconditions* are those in whose absence the effect would never come about, but which are incapable of producing the effect by themselves alone, no matter in what amount they may be present. For the specific cause is still lacking.

The *specific cause* is the one which is never missing in any case in which the effect takes place, and which moreover suffices, if present in the required quantity or intensity, to achieve the effect, provided only that the preconditions are also fulfilled.

As *concurrent causes* we may regard such factors as are not necessarily present every time, nor able, whatever their amount, to produce the effect by themselves alone, but which operate alongside of the preconditions and the specific cause in satisfying the aetiological equation.

The distinctive character of the concurrent, or auxiliary, causes seems clear; but how do we distinguish between a precondition and a specific cause, since both are indispensable and yet neither suffices alone to act as a cause?

The following considerations seem to allow us to arrive at a decision. Among the '*necessary causes*' we find several which reappear in the aetiological equations concerned in many other effects and thus exhibit no special relationship to any one particular effect. One of these causes, however, stands out in contrast to the rest from the fact that it is found in no other aetiological equation, or in very few; and this one has a right to be called the *specific* cause of the effect concerned. Furthermore, preconditions and specific causes are especially distinct from each other in those cases in which the preconditions have the characteristic of being long-standing states that are little susceptible to alteration, while the specific cause is a factor which has recently come into play.

I will try to give an example of this complete aetiological schematic picture:

Effect: Phthisis pulmonum.

Precondition: Disposition, for the most part laid down through heredity, by the organic constitution.

Specific Cause: Bacillus Kochii.

Auxiliary Causes: Anything that diminishes the powers - emotions as well as suppurations or colds.

The schematic picture for the aetiology of anxiety neurosis seems to me to be on the same lines:

Precondition: Heredity.

Specific Cause: A sexual factor, in the sense of a deflection of sexual tension away from the psychical field.

Auxiliary Causes: Any stock noxae - emotion, fright, and also physical exhaustion through illness or over-exertion.

If I consider this aetiological formula for anxiety neurosis in detail, I am able to add the following remarks. Whether a special personal constitution (which need not be produced by heredity) is absolutely necessary for the production of an anxiety neurosis, or whether any normal person can be made to have an anxiety neurosis by some given quantitative increase of the specific factor - this I am not able to decide with certainty; but I incline strongly to the latter view. -Hereditary disposition is the most important precondition for anxiety neurosis; but it is not an *indispensable* one, since it is absent in a class of borderline cases. -The presence of the specific sexual factor can, in the majority of cases, be demonstrated with certainty. In one series of cases (congenital ones) this factor is not separated from the precondition of heredity, but is fulfilled with the help of it. That is to say, in some patients this peculiarity of the *vita sexualis* - psychical inadequacy in mastering somatic sexual tension - is innate in the form of a stigma whereas ordinarily it is *via* that peculiarity that they acquire the neurosis. In another class of borderline cases the specific cause is contained in a contributory one. This is when the psychical inadequacy which I have just mentioned is brought about by exhaustion and such causes. All these cases fall into classes which melt into one another and do not form separate categories. In all of them, moreover, we find that the sexual tension undergoes the same vicissitudes; and for most of them the distinction between precondition, specific and auxiliary cause holds good, in conformity with the solution of the aetiological equation which I have given above.

When I consult my experience on this point, I cannot find that there is any antithetic relation as regards anxiety neurosis between hereditary disposition and the specific sexual factor. On the contrary, the two aetiological factors support and supplement each other. The sexual factor is usually only operative in those who have an innate hereditary taint as well; heredity alone is usually not able to produce an anxiety neurosis, but waits for the occurrence of a sufficient amount of the specific sexual noxa. The discovery of the hereditary element does not, therefore, exempt us from searching for a specific factor. On its discovery, incidentally, all our therapeutic interest as well depends. For what can we do therapeutically about heredity as an aetiological element? It has always been there in the patient and will continue to be there until the end of his life. Taken by itself, it cannot help us to understand the episodic onset of a neurosis or the cessation of a neurosis as a result of treatment. It is nothing but a *precondition* of the neurosis - an inexpressibly important precondition, it is true, but nevertheless one which has been over-estimated, to the detriment of therapy and theoretical comprehension. To be convinced by the contrasting state of affairs, one has only to think of the cases of nervous diseases that run in families (such as chorea chronica, Thomsen's disease, and so on), in which heredity unites in itself all the aetiological preconditions.

In conclusion, I should like to repeat the few statements in which I am accustomed, as a first approximation to the truth, to express the mutual relationships between the various aetiological factors:

(1) Whether a neurotic illness *occurs at all* depends upon a quantitative factor - upon the total load on the nervous system as compared with the latter's capacity for resistance. Everything which can keep this quantitative factor below a certain threshold-value, or can bring it back to that level, has a therapeutic effect, since by so doing it keeps the aetiological equation unsatisfied.

What is to be understood by the 'total load' and by the 'capacity for resistance' of the nervous system, could no doubt be more clearly explained on the basis of certain hypotheses regarding the function of the nerves.

(2) What *dimensions* the neurosis attains depends in the first instance on the amount of the hereditary taint. Heredity acts like a multiplier introduced into an electric circuit, which increases the deviation of the needle many times over.

(3) But what *form* the neurosis assumes - what direction the deviation takes - is solely determined by the specific aetiological factor arising from sexual life.

Although I am aware of the many still unsolved difficulties of the subject, I hope that, on the whole, my hypothesis of an anxiety neurosis will prove more fruitful for an understanding of the neuroses than Löwenfeld's attempt to account for the same facts by postulating '*a combination of neurasthenic and hysterical symptoms in the form of an attack.*'

VIENNA, *beginning of May* 1895.

HEREDITY AND THE AETIOLOGY OF THE NEUROSES
(1896)

Intentionally left blank

HEREDITY AND THE AETIOLOGY OF THE NEUROSES

I am addressing in particular the disciples of J.-M. Charcot, in order to put forward some objections to the aetiological theory of the neuroses which was handed on to us by our teacher.

The role attributed in that theory to nervous heredity is well known: it is the sole true and indispensable cause of neurotic affections, and the other aetiological influences can aspire only to the name of *agents provocateurs*. Such was the opinion laid down by the great man himself and by his pupils, M M. Guinon, Gilles de la Tourette, Janet and others, in regard to the major neurosis, hysteria; and I believe the same view is held in France and in most other places in regard to the other neuroses, though, where these states analogous to hysteria are concerned, it has not been promulgated in so solemn and decided a manner.

I have long entertained doubts on this subject, but I have had to wait to find corroborative facts in my daily experience as a doctor. My objections are now of a double order: factual arguments and arguments derived from speculation. I will begin with the former, arranging them according to the importance I ascribe to them.

I

(a) Affections which are fairly often remote from the domain of neuropathology, and which do not necessarily depend on a disease of the nervous system, have sometimes been regarded as nervous and as showing the presence of a hereditary neuropathic tendency. This has been so with true facial neuralgias and with many headaches which were thought to be nervous but which arose rather from post-infectious pathological changes and suppuration in the pharyngo-nasal cavities. I feel convinced that the patients would benefit if we were more often to hand over the treatment of these affections to the rhinological surgeons.

(b) All the nervous affections found in a patient's family, without consideration of their frequency or severity, have been accepted as a basis for charging him with a hereditary nervous taint. Does not this way of looking at things imply drawing a sharp line between families which are clear of all nervous predisposition and families which are subject to them to an unlimited extent? And do not the facts argue in favour of the contrary view that there are transitions and degrees in nervous disposition and that no family escapes it altogether?

(c) Our opinion of the aetiological role of heredity in nervous illnesses ought decidedly to be based on an impartial statistical examination and not on a *petitio principii*. Until such an examination has been made we ought to believe that the existence of acquired nervous disorders is just as possible as that of hereditary ones. But if there can be nervous disorders that are acquired by people without a predisposition, it can no longer be denied that the nervous affections met with in our patient's relatives may partly have arisen in that way. It will then no longer be possible to quote them as conclusive evidence of the hereditary disposition imputed to the patient by reason of his family history, for a retrospective diagnosis of the illnesses of ancestors or absent members of a family can only very rarely be successfully made.

(d) Those who are adherents of M. Fournier and M. Erb in the matter of the part played by syphilis in the aetiology of tabes dorsalis and progressive paralysis have learned that powerful aetiological influences must be recognized whose collaboration is indispensable for the pathogenesis of certain illnesses which could not be produced by heredity alone. Nevertheless M. Charcot remained to the very last (as I know from a private letter I had from him) strictly opposed to Fournier's theory, which is, however, gaining ground every day.

(e) There is no doubt that certain nervous disorders can develop in people who are perfectly healthy and whose family is above reproach. This is a matter of daily observation in cases of Beard's neurasthenia; if neurasthenia were restricted to people who were predisposed, it would never have attained the importance and extent with which we are familiar.

(f) In nervous pathology there is *similar heredity* and what is known as *dissimilar heredity*. No objection can be made to the former; it is in fact a very remarkable thing that in the disorders which depend on similar heredity (Thomsen's disease, Friedreich's disease, the myopathies, Huntington's chorea, etc.) we never come across a trace of any other accessory aetiological influence. But dissimilar heredity, which is much more important than the other, leaves gaps which would have to be filled before a satisfactory solution of aetiological problems could be reached. Dissimilar heredity consists in the fact that the members of the same family are found to be affected by the most various nervous disorders, functional and organic, without its being possible to discover any law determining the replacement of one illness by another or the order of their succession through the generations. Alongside of the sick members of these families there are others who remain healthy; and the theory of dissimilar heredity does not tell us why one person tolerates the same hereditary load without succumbing to it or why another person, who is sick, should choose this particular nervous affection from among all the illnesses which make up the great family of nervous diseases instead of choosing another one - hysteria instead of epilepsy or insanity, and so on. Since there is no such thing as chance in neurotic pathogenesis any more than anywhere else, it must be allowed that it is not heredity that presides over the choice of the particular nervous disorder which is to develop in the predisposed member of a family, but that there are grounds for suspecting the existence of other aetiological influences, of a less incomprehensible nature, which would then deserve to be called the *specific aetiology* of such and such a nervous affection. Without the existence of this special aetiological factor, heredity could have done nothing; it would have lent itself to the production of another nervous disorder if the specific aetiology in question had been replaced by some other influence.

II

There has been too little research into these specific and determining causes of nervous disorders, for the attention of physicians has remained dazzled by the grandiose prospect of the aetiological precondition of heredity. Those causes nevertheless deserve to be made the object of industrious study. Although their pathogenic power is in general only accessory to that of heredity, great practical interest attaches to the knowledge of this specific aetiology; it will allow our therapeutic efforts a path of access, whereas hereditary disposition, which is something fixed in advance for the patient from his birth, brings our efforts to a halt with its unapproachable power.

I have been engaged for years in researches into the aetiology of the major neuroses (functional nervous states analogous to hysteria) and it is the result of those studies that I propose to describe to you in the following pages. To avoid any possible misunderstanding I shall begin by making two remarks on the nosography of the neuroses and on the aetiology of the neuroses in general.

I was obliged to begin my work with a nosographic innovation. I found reason to set alongside of hysteria the obsessional neurosis (*Zwangsneurose*) as a self-sufficient and independent disorder, although the majority of the authorities place obsessions among the syndromes constituting mental degeneracy or confuse them with neurasthenia. I for my part, by examining the psychical mechanism of obsessions, had learnt that they are connected with hysteria more closely than one might suppose.

Hysteria and obsessional neurosis form the first group of the major neuroses studied by me. The second contains Beard's neurasthenia, which I have divided up into two functional states separated by their aetiology as well as by their symptomatic appearance - *neurasthenia* proper and the *anxiety neurosis* (*Angstneurose*), a name which, I may say in passing, I am not pleased with myself. I gave my detailed reasons for making this separation, which I consider necessary, in a paper published in 1895.

As regards the aetiology of the neuroses, I think it should be recognized in theory that aetiological influences, differing among themselves in their importance and in the manner in which they are related to the effect they produce, can be grouped in three classes: (1) *Preconditions*, which are indispensable for producing the disorder concerned but which are of a general nature and are equally met with in the aetiology of many other disorders; (2) *Concurrent Causes*, which share the character of preconditions in that they function in the causation of other disorders as well as in that of the disorder under consideration, but which are not indispensable for the production of the latter; and (3) *Specific Causes*, which are as indispensable as the preconditions, but are of a limited nature and appear only in the aetiology of the disorder for which they are specific.

In the pathogenesis of the major neuroses, then, heredity fulfils the role of a *precondition*, powerful in every case and even indispensable in most cases. It could not do without the collaboration of the specific causes; but the importance of hereditary disposition is proved by the fact that the same specific causes acting on a healthy individual produce no manifest pathological effect, whereas in a predisposed person their action causes the neurosis to come to light, whose development will be proportionate in intensity and extent to the degree of the hereditary precondition.

Thus the action of heredity is comparable to that of a multiplier in an electric circuit, which exaggerates the visible deviation of the needle, but which cannot determine its direction.

There is yet another thing to be noted in the relations between the hereditary precondition and the specific causes of neuroses. Experience shows - what one might have guessed in advance - that in these questions of aetiology one should not neglect the relative quantities, so to speak, of the aetiological influences. But one could not have guessed the following fact, which seems to arise from my observations: namely that heredity and the specific causes can replace each other as regards quantity, that the same pathological effect will be produced by the coincidence of a very serious specific aetiology with a moderate disposition or of a severely loaded nervous heredity with a slight specific influence. And we shall simply be meeting not unexpected extreme instances in this series if we come upon cases of neurosis in which we shall look in vain for an appreciable degree of hereditary disposition, provided that what is lacking is made up for by a powerful specific influence.

As *concurrent* (or auxiliary) *causes* of neuroses may be enumerated all the stock agents met with elsewhere: emotional disturbance, physical exhaustion, acute illnesses, intoxications, traumatic accidents, intellectual overwork, etc. I maintain that none of these, not even the last, enters into the aetiology of the neuroses regularly or necessarily, and I am aware that to declare this opinion is to put oneself in direct opposition to a theory which is looked upon as universally accepted and irreproachable. Since Beard declared that neurasthenia was the fruit of our modern civilization, he has only met with believers; but I find it impossible to accept this view. A laborious study of the neuroses has taught me that the specific aetiology of the neuroses has escaped Beard's notice.

I have no desire to depreciate the aetiological importance of these stock agents. Since they are very various, occur very frequently and are most often named by patients themselves, they become more prominent than the specific causes of the neuroses - an aetiology which is either hidden or unknown. Fairly frequently they fulfil the function of *agents provocateurs* which render manifest a neurosis that has previously been latent; and a practical interest attaches to them, for a consideration of these stock causes may offer lines of approach to a therapy which does not aim at a radical cure and is content with repressing the illness to its former state of latency.

But it is not possible to establish any constant and close relation between one of these stock causes and one or other form of nervous affection. Emotional disturbance, for instance, is found equally in the aetiology of hysteria, obsessions and neurasthenia, as well as in that of epilepsy, Parkinson's disease, diabetes and many others.

Stock concurrent causes can replace the specific aetiology in respect of quantity, but can never take its place entirely. There are numerous cases in which all the aetiological influences are represented by the hereditary precondition and the specific cause, stock causes being absent. In the other cases indispensable aetiological factors are not in themselves sufficient in quantity to bring about an outbreak of neurosis; a state of apparent health may be maintained for a long time, though it is in reality a state of predisposition to neurosis. It is then enough for a stock cause to come into action as well, and the neurosis becomes manifest. But it must be clearly pointed out that under these conditions the nature of the stock cause which supervenes is a matter of complete indifference - whether it is an emotion, a trauma, an infectious illness or anything else. The pathological effect will not be modified according to this variation; the nature of the neurosis will always be dominated by the pre-existing specific cause.

What, then are the specific causes of neuroses? Is there a single one or are there several? And is it possible to establish a constant aetiological relation between a particular cause and a particular neurotic effect, in such a way that each of the major neuroses can be attributed to a special aetiology?

On the basis of a laborious examination of the facts, I shall maintain that this last supposition is quite in agreement with reality, that each of the major neuroses which I have enumerated has as its immediate cause one particular disturbance of the economics of the nervous system, and that these functional pathological modifications *have as their common source the subject's sexual life, whether they lie in a disorder of his contemporary sexual life or in important events in his past life.*

This, to tell the truth, is no new, unheard-of proposition. Sexual disorders have always been admitted among the causes of nervous illness, but they have been subordinated to heredity - and co-ordinated with the other *agents provocateurs*; their aetiological influence has been restricted to a limited number of observed cases. Physicians had even fallen into the habit of not investigating them unless the patient brought them up himself. What gives its distinctive character to my line of approach is that I elevate these sexual influences to the rank of specific causes, that I recognize their action in every case of neurosis, and finally that I trace a regular parallelism, a proof of a special aetiological relation between the nature of the sexual influence and the pathological species of the neurosis.

I am quite sure that this theory will call up a storm of contradictions from contemporary physicians. But this is not the place in which to present the documents and the experiences which have forced me to my convictions, nor to explain the true meaning of the rather vague expression 'disorders of the economics of the nervous system'. This will be done, most fully, I hope, in a work on the subject which I have in preparation. In the present paper I limit myself to reporting my findings.

Neurasthenia proper, if we detach anxiety neurosis from it, has a very monotonous clinical appearance: fatigue, intracranial pressure, flatulent dyspepsia, constipation, spinal paraesthesias, sexual weakness, etc. The only specific aetiology it allows of is (immoderate) masturbation or spontaneous emissions.

It is the prolonged and intense action of this pernicious sexual satisfaction which is enough on its own account to provoke a neurasthenic neurosis or which imposes on the subject the special neurasthenic stamp that is manifested later under the influence of an incidental accessory cause. I have also come across people presenting the indications of a neurasthenic constitution in whom I have not succeeded in bringing to light the aetiology I have mentioned; but I have at least shown that the sexual function has never developed to its normal level in these patients; they seemed to have been endowed by heredity with a sexual constitution analogous to what is brought about in a neurasthenic as a result of masturbation.

The anxiety neurosis exhibits a much richer clinical picture: irritability, states of anxious expectation, phobias, anxiety attacks, complete or rudimentary, attacks of fear and of vertigo, tremors, sweating, congestion, dyspnoea, tachycardia, etc., chronic diarrhoea, chronic locomotor vertigo, hyperaesthesia, insomnia, etc.¹ It is easily revealed as being the specific effect of various disorders of sexual life which possess a characteristic common to all of them. Enforced abstinence, unconsummated genital excitation (excitation which is not relieved by a sexual act), coition which is imperfect or interrupted (which does not end in gratification), sexual efforts which exceed the subject's psychical capacity, etc. - all these agents, which occur only too frequently in modern life, seem to agree in the fact that they disturb the equilibrium of the psychical and somatic functions in sexual acts, and that they prevent the psychical participation necessary in order to free the nervous economy from sexual tension.

¹ For the symptomatology as well as for the aetiology of anxiety neurosis, see my paper referred to above.

These remarks, which perhaps contain the germ of a theoretical explanation of the functional mechanism of the neurosis in question, give rise already to a suspicion that a complete and truly scientific exposition of the subject is not possible at the present time, and that it would be necessary to start off by approaching the physiological problem of sexual life from a fresh angle.

I will say finally that the pathogenesis of neurasthenia and anxiety neurosis can easily do without the co-operation of a hereditary disposition. That is the outcome of daily observation. But if heredity is present, the development of the neurosis will be affected by its powerful influence.

As regards the second class of major neuroses, hysteria and obsessional neurosis, the solution of the aetiological problem is of surprising simplicity and uniformity. I owe my results to a new method of psycho-analysis, Josef Breuer's exploratory procedure; it is a little intricate, but it is irreplaceable, so fertile has it shown itself to be in throwing light upon the obscure paths of unconscious ideation. By means of that procedure - this is not the place in which to describe it ¹ - hysterical symptoms are traced back to their origin, which is always found in some event of the subject's sexual life appropriate for the production of a distressing emotion. Travelling backwards into the patient's past, step by step, and always guided by the organic train of symptoms and of memories and thoughts aroused, I finally reached the starting-point of the pathological process; and I was obliged to see that at bottom the same thing was present in all the cases submitted to analysis - the action of an agent which must be accepted as the specific cause of hysteria.

¹ See *Studies on Hysteria*, by Breuer and Freud, 1895.

This agent is indeed a memory relating to sexual life; but it is one which presents two characteristics of the first importance. The event of which the subject has retained an unconscious memory is a *precocious experience of sexual relations with actual excitement of the genitals, resulting from sexual abuse committed by another person*; and the period of life at which this fatal event takes place is *earliest youth* - the years up to the age of eight to ten, before the child has reached sexual maturity.

A passive sexual experience before puberty: this, then, is the specific aetiology of hysteria.

I will without delay add some factual details and some commentary to the result I have announced, in order to combat the scepticism with which I expect to meet. I have been able to carry out a complete psycho-analysis in thirteen cases of hysteria, three of that number being true combinations of hysteria and obsessional neurosis. (I do not speak of hysteria *with* obsessions.) In none of these cases was an event of the kind defined above missing. It was represented either by a brutal assault committed by an adult or by a seduction less rapid and less repulsive, but reaching the same conclusion. In seven out of the thirteen cases the intercourse was between children on both sides - sexual relations between a little girl and a boy a little older (most often her brother) who had himself been the victim of an earlier seduction. These relations sometimes continued for years, until the little guilty parties reached puberty; the boy would repeat the same practices with the little girl over and over again and without alteration - practices to which he himself had been subjected by some female servant or governess and which on account of their origin were often of a disgusting sort. In a few cases there was a combination of an assault and relations between children or a repetition of a brutal abuse.

The date of this precocious experience varied. In two cases the series started in the little creature's second year (?); the commonest age in my observations is the fourth or fifth year. It may be somewhat by accident, but I have formed an impression from this that a passive sexual experience occurring only after the age of from eight to ten is no longer able to serve as the foundation of the neurosis.

How is it possible to remain convinced of the reality of these analytic confessions which claim to be memories preserved from the earliest childhood? and how is one to arm oneself against the tendency to lies and the facility of invention which are attributed to hysterical subjects? I should accuse myself of blame-worthy credulity if I did not possess more conclusive evidence. But the fact is that these patients never repeat these stories spontaneously, nor do they ever in the course of a treatment suddenly present the physician with the complete recollection of a scene of this kind. One only succeeds in awakening the psychical trace of a precocious sexual event under the most energetic pressure of the analytic procedure, and against an enormous resistance. Moreover, the memory must be extracted from them piece by piece, and while it is being awakened in their consciousness they become the prey to an emotion which it would be hard to counterfeit.

Conviction will follow in the end, if one is not influenced by the patients' behaviour, provided that one can follow in detail the report of a psycho-analysis of a case of hysteria.

The precocious event has left an indelible imprint on the history of the case; it is represented in it by a host of symptoms and of special features which could be accounted for in no other way; it is peremptorily called for by the subtle but solid interconnections of the intrinsic structure of the neurosis; the therapeutic effect of the analysis lags behind if one has not penetrated so far; and one is then left with no choice but to reject or to believe the whole.

Is it understandable that a precocious sexual experience of this kind, undergone by an individual whose sex is barely differentiated, can become the source of a persistent psychical abnormality like hysteria? And how would this supposition fit in with our present ideas on the psychical mechanism of that neurosis? A satisfactory reply can be given to the first of these questions. It is precisely because the subject is in his infancy that the precocious sexual excitation produces little or no effect at the time; but its psychical trace is preserved. Later, when at puberty the reactions of the sexual organs have developed to a level incommensurable with their infantile condition, it comes about in one way or another that this unconscious psychical trace is awakened. Thanks to the change due to puberty, the memory will display a power which was completely lacking from the event itself. *The memory will operate as though it were a contemporary event.* What happens is, as it were, *a posthumous action by a sexual trauma.*

So far as I can see, this awakening of a sexual memory after puberty, when the event itself has happened at a time long before that period, forms the only psychological instance of the effect of a *memory* surpassing that of an actual event. But the constellation is an abnormal one, which touches a weak side of the psychical mechanism and is bound to produce a pathological psychical effect.

I believe I can see that *this inverse relation between the psychical effect of the memory and of the event* contains the reason for *the memory remaining unconscious.*

In this way we arrive at a very complex psychical problem, but one which, properly appreciated, promises to throw a vivid light on the most delicate questions of psychical life.

The ideas put forward here, which have as their starting point the finding of psycho-analysis to the effect that a memory of a precocious sexual experience is always found as the specific cause of hysteria, are not in harmony with the psychological theory of neuroses held by M. Janet, nor with any other; but they agree perfectly with my own speculations on the '*Abwehrneurosen*', as I have developed them elsewhere.

All the events subsequent to puberty to which an influence must be attributed upon the development of the hysterical neurosis and upon the formation of its symptoms are in fact only concurrent causes - '*agents provocateurs*' as Charcot used to say, although for him nervous heredity occupied the place which I claim for the precocious sexual experience. These accessory agents are not subject to the strict conditions imposed on the specific causes; analysis demonstrates in an irrefutable fashion that they enjoy a pathogenic influence for hysteria only owing to their faculty for awakening the unconscious psychical trace of the childhood event. It is also thanks to their connection with the primary pathogenic impression, and inspired by it, that their memories will become unconscious in their turn and will be able to assist in the growth of a psychical activity withdrawn from the power of the conscious functions.

The obsessional neurosis (*Zwangsneurose*) arises from a specific cause very analogous to that of hysteria. Here too we find a precocious sexual event, occurring before puberty, the memory of which becomes active during or after that period; and the same remarks and arguments which I put forward in connection with hysteria will apply to my observations of the other neurosis (six cases, three of which were pure ones). There is only one difference which seems capital. At the basis of the aetiology of hysteria we found an event of passive sexuality, an experience submitted to with indifference or with a small degree of annoyance or fright. In obsessional neurosis it is a question on the other hand, of an event which has given *pleasure*, of an act of aggression inspired by desire (in the case of a boy) or of a participation in sexual relations accompanied by enjoyment (in the case of a little girl). The obsessional ideas, when their intimate meaning has been recognized by analysis, when they have been reduced, as it were, to their simplest expression, are nothing other than *reproaches addressed by the subject himself on account of this anticipated sexual enjoyment*, but reproaches distorted by an unconscious psychical work of transformation and substitution.

The very fact of sexual aggressions of this kind taking place at such a tender age seems to reveal the influence of a previous seduction of which the precocity of sexual desire would be the consequence. In the cases analysed by me analysis confirms this suspicion. In this way an interesting fact is explained which is always found in these cases of obsessions: the regular complication of the framework of symptoms by a certain number of symptoms which are simply hysterical.

The importance of the active element in sexual life as a cause of obsessions, and of sexual passivity for the pathogenesis of hysteria, even seems to unveil the reason for the more intimate connection of hysteria with the female sex and the preference of men for obsessional neurosis. One sometimes comes across a pair of neurotic patients who were a pair of little lovers in their earliest childhood - the man suffering from obsessions and the woman from hysteria. If they are a brother and sister, one might mistake for a result of nervous heredity what is in fact the consequence of precocious sexual experiences.

There are no doubt pure and isolated cases of hysteria or obsessions, independent of neurasthenia or anxiety neurosis; but this is not the rule. A psychoneurosis appears more often as an accessory to a neurasthenic neurosis, provoked by it and following its decline. This is because the specific causes of the latter, the contemporary disorders of sexual life, operate at the same time as auxiliary causes of the psychoneuroses, whose specific cause, the memory of the precocious sexual experience, they awaken and revive.

As regards nervous heredity, I am far from being able to estimate correctly its influence in the aetiology of the psychoneuroses. I admit that its presence is indispensable for severe cases; I doubt if it is necessary for slight ones; but I am convinced that nervous heredity by itself is unable to produce psychoneuroses if their specific aetiology, precocious sexual excitation, is missing. I even believe that the decision as to which of the neuroses, hysteria or obsessions, will develop in a given case, is not decided by heredity but a special characteristic of the sexual event in earliest childhood.

FURTHER REMARKS ON THE NEURO-PSYCHOSES OF DEFENCE
(1896)

Intentionally left blank

FURTHER REMARKS ON THE NEURO-PSYCHOSES OF DEFENCE

In a short paper published in 1894, I grouped together hysteria, obsessions and certain cases of acute hallucinatory confusion under the name of 'neuro-psychoses of defence', because those affections turned out to have one aspect in common. This was that their symptoms arose through the psychical mechanism of (unconscious) *defence* - that is, in an attempt to repress an incompatible idea which had come into distressing opposition to the patient's ego. In some passages in a book which has since appeared by Dr. J. Breuer and myself (*Studies on Hysteria*) I have been able to elucidate, and to illustrate from clinical observations, the sense in which this psychical process of 'defence' or 'repression' is to be understood. There, too, some information is to be found about the laborious but completely reliable method of psycho-analysis used by me in making those investigations - investigations which also constitute a therapeutic procedure.

My observations during my last two years of work have strengthened me in the inclination to look on defence as the nuclear point in the psychical mechanism of the neuroses in question; and they have also enabled me to give this psychological theory a clinical foundation. To my own surprise, I have come upon a few simple, though narrowly circumscribed, solutions of the problems of neurosis, and in the following pages I shall give a preliminary and brief account of them. In this kind of communication it is not possible to bring forward the evidence needful to support my assertions, but I hope to be able to fulfil this obligation later in a detailed presentation.

I

THE 'SPECIFIC' AETIOLOGY OF HYSTERIA

In earlier publications, Breuer and I have already expressed the opinion that the symptoms of hysteria can only be understood if traced back to experiences which have a 'traumatic' effect, and that these psychical traumas refer to the patient's sexual life. What I have to add here, as a uniform outcome of the analyses carried out by me on thirteen cases of hysteria, concerns on the one hand the *nature* of those sexual traumas, and, on the other, the period of life in which they occur. In order to cause hysteria, it is not enough that there should occur at some period of the subject's life an event which touches his sexual existence and becomes pathogenic through the release and suppression of a distressing affect. On the contrary, *these sexual traumas must have occurred in early childhood (before puberty), and their content must consist of an actual irritation of the genitals (of processes resembling copulation).*

I have found this specific determinant of hysteria - *sexual passivity during the pre-sexual period* - in every case of hysteria (including two male cases) which I have analysed. How greatly the claims of hereditary disposition are diminished by the establishment in this way of accidental aetiological factors as a determinant needs no more than a mention. Furthermore, a path is laid open to an understanding of why hysteria is far and away more frequent in members of the female sex; for even in childhood they are more liable to provoke sexual attacks.

The most immediate objections to this conclusion will probably be that sexual assaults on small children happen too often for them to have any aetiological importance, or that these sorts of experiences are bound to be without effect precisely because they happen to a person who is sexually undeveloped; and further, that one must beware of forcing on patients supposed reminiscences of this kind by questioning them, or of believing in the romances which they themselves invent. In reply to the latter objections we may ask that no one should form too certain judgements in this obscure field until he has made use of the only method which can throw light on it - of psycho-analysis for the purpose of making conscious what has so far been unconscious.¹ What is essential in the first objections can be disposed of by pointing out that it is not the experiences themselves which act traumatically their revival as a *memory* after the subject has entered on sexual maturity.

My thirteen cases were without exception of a severe kind; in all of them the illness was of many years' duration, and a few came to me after lengthy and unsuccessful institutional treatment. The childhood traumas which analysis uncovered in these severe cases had all to be classed as grave sexual injuries; some of them were positively revolting. Foremost among those guilty of abuses like these, with their momentous consequences, are nursemaids, governesses and domestic servants, to whose care children are only too thoughtlessly entrusted; teachers, moreover, figure with regrettable frequency. In seven out of these thirteen cases, however, it turned out that blameless children were the assailants; these were mostly brothers who for years on end had carried on sexual relations with sisters a little younger than themselves. No doubt the course of events was in every instance similar to what it was possible to trace with certainty in a few individual cases: the boy, that is to say, had been abused by someone of the female sex, so that his libido was prematurely aroused, and then, a few years later, he had committed an act of sexual aggression against his sister, in which he repeated precisely the same procedures to which he himself had been subjected.

¹ I myself am inclined to think that the stories of being assaulted which hysterics so frequently invent may be obsessional fictions which arise from the memory-trace of a childhood trauma.

Active masturbation must be excluded from my list of the sexual noxae in early childhood which are pathogenic for hysteria. Although it is found so very often side by side with hysteria, this is due to the circumstance that masturbation itself is a much more frequent consequence of abuse or seduction than is supposed.

It is not at all rare for both of the two children to fall ill later on of a defence neurosis - the brother with obsessions and the sister with hysteria. This naturally gives the appearance of a familial neurotic disposition. Occasionally, however, this pseudo-heredity is resolved in a surprising fashion. In one of my cases a brother, a sister, and a somewhat older male cousin were all of them ill. From the analysis which I carried out on the brother, I learnt that he was suffering from self-reproaches for being the cause of his sister's illness. He himself had been seduced by his cousin, and the latter, it was known in the family, had been the victim of his nursemaid.

I cannot say for certain what the upper age-limit is below which sexual injury plays a part in the aetiology of hysteria; but I doubt whether sexual passivity can bring on repression later than between the eighth and tenth years, unless it is enabled to do so by previous experiences. The lower limit extends as far back as memory itself - that is, therefore, to the tender age of one and a half or two years! (I have had two cases of this.) In a number of my cases the sexual trauma (or series of traumas) occurred in the third and fourth years of life. I should not lend credence to these extraordinary findings myself if their complete reliability were not proved by the development of the subsequent neurosis. In every case a number of pathological symptoms, habits and phobias are only to be accounted for by going back to these experiences in childhood, and the logical structure of the neurotic manifestations makes it impossible to reject these faithfully preserved memories which emerge from childhood life. True, it would be useless to try to elicit these childhood traumas from a hysteric by questioning him outside psycho-analysis; their traces are never present in conscious memory, only in the symptoms of the illness.

All the experiences and excitations which, in the period of life *after* puberty, prepare the way for, or precipitate, the outbreak of hysteria, *demonstrably* have their effect only because they arouse the memory-trace of these traumas in childhood, which do not thereupon become conscious but lead to a release of affect and to repression. This role of the later traumas tallies well with the fact that they are not subject to the strict conditions which govern the traumas in childhood but that they can vary in their intensity and nature, from actual sexual violation to mere sexual overtures or the witnessing of sexual acts in other people, or receiving information about sexual processes.¹

In my first paper on the neuroses of defence there was no explanation of how the efforts of the subject, who had hitherto been healthy, to forget a traumatic experience of this sort could have the result of actually effecting the intended repression and thus opening the door to the defence neurosis. It could not lie in the nature of the experiences, since other people remained healthy in spite of being exposed to the same precipitating causes. Hysteria, therefore, could not be fully explained from the effect of the trauma: it had to be acknowledged that the susceptibility to a hysterical reaction had already existed before the trauma.

The place of this indefinite hysterical disposition can now be taken, wholly or in part, by the posthumous operation of a sexual trauma in childhood. 'Repression' of the memory of a distressing sexual experience which occurs in maturer years is only possible for those in whom that experience can activate the memory-trace of a trauma in childhood.

¹ In a paper on the anxiety neurosis, I remarked that 'anxiety neurosis can be produced in girls who are approaching maturity by their first encounter with the problem of sex. . . . Such an anxiety neurosis is combined with hysteria in an almost typical fashion.' I know now that the occasion on which this 'virginal anxiety' breaks out in young girls does not actually represent their *first* encounter with sexuality, but that an experience of sexual passivity had previously occurred in their childhood, the memory of which is aroused by this 'first encounter'.

² A psychological theory of repression ought also to throw light on the question of why it is only ideas with a *sexual* content that can be repressed. Such an explanation might start out from the following indications. It is known that having ideas with a sexual content produces excitatory processes in the genitals which are similar to those produced by sexual experience itself. We may assume that this somatic excitation becomes transposed into the psychical sphere. As a rule the effect in question is much stronger in the case of the experience than in the case of the memory. But if the sexual experience occurs during the period of sexual immaturity and the memory of it is aroused during or after maturity, then the memory will have a far stronger excitatory effect than the experience did at the time it happened; and this is because in the meantime puberty has immensely increased the capacity of the sexual apparatus for reaction. An inverted relation of this sort between real experience and memory seems to contain the psychological precondition for the occurrence of a repression. Sexual life affords - through the retardation of pubertal maturity as compared with the psychical functions - the only possibility that occurs for this inversion of relative effectiveness. *The traumas of childhood operate in a deferred fashion as though they were fresh experiences; but they do so unconsciously.* I must postpone entering into any more far-reaching psychological discussion till another occasion. Let me add, however, that the period of 'sexual maturity' which is in question here does not coincide with puberty but falls earlier (from the eighth to the tenth year).

Obsessions similarly presuppose a sexual experience in childhood (though one of a different nature from that found in hysteria). The aetiology of the two neuro-psychoses of defence is related as follows to the aetiology of the two simple neuroses, neurasthenia and anxiety neurosis. Both the latter disorders are direct effects of the sexual noxae themselves, as I have shown in my paper on anxiety neurosis (1895*b*); both the defence neuroses are indirect consequences of sexual noxae which have occurred before the advent of sexual maturity - are consequences, that is, of the psychical memory-traces of those noxae. The current causes which produce neurasthenia and anxiety neurosis often at the same time play the part of exciting causes of the neuroses of defence; on the other hand, the specific causes of a defence-neurosis - the traumas of childhood - can at the same time lay the foundations for a later development of neurasthenia. Finally, it not infrequently happens, too, that neurasthenia or anxiety neurosis is maintained, not by current sexual noxae, but, instead, solely by the persisting effect of a memory of childhood traumas.¹

II

THE NATURE AND MECHANISM OF OBSESSIONAL NEUROSIS

Sexual experiences of early childhood have the same significance in the aetiology of obsessional neurosis as they have in that of hysteria. Here, however, it is no longer a question of sexual *passivity*, but of acts of aggression carried out with pleasure and of pleasurable participation in sexual acts - that is to say, of sexual *activity*. This difference in the aetiological circumstances is bound up with the fact that obsessional neurosis shows a visible preference for the male sex.

¹ (*Footnote added 1924:*) This section is dominated by an error which I have since repeatedly acknowledged and corrected. At that time I was not yet able to distinguish between my patients' phantasies about their childhood years and their real recollections. As a result, I attributed to the aetiological factor of seduction a significance and universality which it does not possess. When this error had been overcome, it became possible to obtain an insight into the spontaneous manifestations of the sexuality of children which I described in my *Three Essays on the Theory of Sexuality* (1905*d*). Nevertheless, we need not reject everything written in the text above. Seduction retains a certain aetiological importance, and even to-day I think some of these psychological comments are to the point.

In all my cases of obsessional neurosis, moreover, I have found a *substratum of hysterical symptoms* which could be traced back to a scene of sexual passivity that preceded the pleasurable action. I suspect that this coincidence is no fortuitous one, and that precocious sexual aggressivity always implies a previous experience of being seduced. However, I can as yet give no definitive account of the aetiology of obsessional neurosis; I only have an impression that the decision as to whether hysteria or obsessional neurosis will arise on the basis of traumas in childhood depends on *chronological* circumstances in the development of the libido.

The nature of obsessional neurosis can be expressed in a simple formula. *Obsessional ideas* are invariably transformed *self-reproaches* which have re-emerged from *repression* and which always relate to some *sexual* act that was performed with pleasure *in childhood*. In order to elucidate this statement it is necessary to describe the typical course taken by an obsessional neurosis.

In a first period - the period of childhood immorality - the events occur which contain the germ of the later neurosis. First of all, in earliest childhood, we have the experiences of sexual seduction that will later on make repression possible; and then come the acts of sexual aggression against the other sex, which will later appear in the form of acts involving self-reproach.

This period is brought to a close by the advent of sexual 'maturation', often itself unduly early. A self-reproach now becomes attached to the memory of these pleasurable actions; and the connection with the initial experience of passivity makes it possible - often only after conscious and remembered efforts - to repress them and to replace them by a *primary symptom of defence*. Conscientiousness, shame and self-distrust are symptoms of this kind, with which the third period begins - the period of *apparent* health, but actually, of successful defence.

The next period, that of the illness, is characterized by *return of the repressed memories* - that is, therefore, by the failure of the defence. It is not certain whether the awakening of those memories occurs more often accidentally and spontaneously or as a result of current sexual disturbances, as a kind of by-product of them. The re-activated memories, however, and the self reproaches formed from them never re-emerge into consciousness unchanged: what become conscious as obsessional ideas and affects, and take the place of the pathogenic memories so far as conscious life is concerned, are structures in the nature of a *compromise* between the repressed ideas and the repressing ones.

In order to describe clearly and with probable accuracy the processes of repression, the return of the repressed and the formation of pathological compromise-ideas, one would have to make up one's mind to quite definite assumptions about the substratum of psychical events and of consciousness. So long as one seeks to avoid this, one must be content with the following remarks which are intended more or less figuratively. There are two forms of obsessional neurosis, according to whether what forces an entrance into consciousness is solely the *mnemic content* of the act involving self-reproach, or whether the self-reproachful *affect* connected with the act does so as well.

The first form includes the typical obsessional ideas, in which the content engages the patient's attention and, as an affect, he merely feels an indefinite unpleasure, whereas the only affect which would be suitable to the obsessional idea would be one of self-reproach. The content of the obsessional idea is distorted in two ways in relation to the obsessional act of childhood. First, something contemporary is put in the place of something past; and secondly, something sexual is replaced by something analogous to it that is not sexual. These two alterations are the effect of the inclination to repress, still in force, which we will ascribe to the 'ego'. The influence of the re-activated pathogenic memory is shown by the fact that the content of the obsessional idea is still in part identical with what has been repressed or follows from it by a logical train of thought. If, with the help of the psycho-analytic method, we reconstruct the origin of an individual obsessional idea, we find that from a single current impression two different trains of thought have been set going. The one which has passed by way of the repressed memory proves to be as correctly logical in its structure as the other, although it is incapable of being conscious and insusceptible to correction. If the products of the two psychical operations do not tally, what takes place is not some sort of logical adjustment of the contradiction between them; instead, alongside of the *normal* intellectual outcome, there comes into consciousness, as a compromise between the resistance and the *pathological* intellectual product, an obsessional idea which appears absurd. If the two trains of thought lead to the *same* conclusion, they reinforce each other, so that an intellectual product that has been arrived at normally now behaves, psychologically, like an obsessional idea. *Wherever a neurotic obsession emerges in the psychological sphere, it comes from repression.* Obsessional ideas have, as it were, a compulsive psychical currency, not on account of their intrinsic value, but on account of the source from which they derive or which has added a contribution to their value.

A second form of obsessional neurosis comes about if what has forced its way to representation in conscious psychical life is not the repressed mnemic content but the likewise repressed self-reproach. The affect of self-reproach can, by means of some mental addition, be transformed into any other unpleasurable affect. When this has happened there is no longer anything to prevent the substituted affect from becoming conscious. Thus *self-reproach* (for having carried out the sexual act in childhood) can easily turn into *shame* (in case some one else should find out about it), into *hypochondriacal anxiety* (fear of the physical injuries resulting from the act involving the self-reproach), into *social anxiety* (fear of being punished by society for the misdeed), into *religious anxiety*, into *delusions of being noticed* (fear of betraying the act to other people), or into *fear of temptation* (a justified mistrust of one's own moral powers of resistance), and so on. In addition, the mnemic content of the act involving self-reproach may be represented in consciousness as well, or it may remain completely in the background - which makes diagnosis much more difficult. Many cases which, on a superficial examination, seem to be common (neurasthenic) hypochondria, belong to this group of *obsessional affects*; what is known as 'periodic neurasthenia' or 'periodic melancholia' seems in particular to resolve itself with unexpected frequency into obsessional affects and obsessional ideas - a discovery which is not a matter of indifference therapeutically.

Besides these compromise symptoms, which signify the return of the repressed and consequently a collapse of the defence that had been originally achieved, the obsessional neurosis constructs a set of further symptoms, whose origin is quite different. For the ego seeks to fend off the derivatives of the initially repressed memory, and in this defensive struggle it creates symptoms which might be classed together as '*secondary defence*'. These are all of them '*protective measures*', which have already done good service in the fight against obsessional ideas and obsessional affects. If these aids in the defensive struggle *genuinely* succeed in once more repressing the symptoms of the return which have forced themselves on the ego, then the obsession is transferred to the protective measures themselves and creates a third form of 'obsessional neurosis' - *obsessional actions*. These actions are never primary; they never contain anything but a defence - never an aggression. A psychical analysis of them shows that, in spite of their peculiarity, they can always be fully explained by being traced back to the obsessional memories which they are fighting against.¹

¹ To take a single example only. An eleven-year-old boy had in an obsessional way instituted the following ceremonial before going to bed. He did not go to sleep until he had told his mother in the minutest detail all the experiences he had had during the day; there must be no bits of paper or other rubbish on the carpet in his bedroom in the evening; his bed had to be pushed right up against the wall, three chairs had to be placed in front of it, and the pillows had to lie in a particular way. In order to go to sleep he was obliged first to kick both his legs out a certain number of times and then lie on his side. This was explained in the following manner. Years before, a servant-girl who put the nice looking boy to bed had taken the opportunity of lying down on him and abusing him sexually. When, later on, this memory was aroused in him by a recent experience, it manifested itself in his consciousness in a compulsion to perform the ceremonial I have described above. The meaning of the ceremonial was easy to guess and was established point by point by psycho-analysis. The chairs were placed in front of the bed and the bed pushed against the wall in order that nobody else should be able to get at the bed; the pillows were arranged in a particular way so that they should be differently arranged from how they were on that evening; the movements with his legs were to kick away the person who was lying on him; sleeping on his side was because in the scene he had been lying on his back; his circumstantial confession to his mother was because, in obedience to a prohibition by his seductress, he had been silent to his mother about this and other sexual experiences; and, finally, the reason for his keeping his bedroom floor clean was that neglect to do so had been the chief reproach that he had so far had to hear from his mother.

Secondary defence against the obsessional ideas may be effected by a forcible diversion on to other thoughts with a content as contrary as possible. This is why *obsessional brooding*, if it succeeds, regularly deals with abstract and *suprasensual* things; because the ideas that have been repressed are always concerned with *sensuality*. Or else the patient tries to make himself master of each of his obsessional ideas singly by logical work and by having recourse to his conscious memories. This leads to *obsessional thinking*, to a *compulsion to test things* and to *doubting mania*. The advantage which perception has over memory in such tests at first causes the patient, and later compels him, to collect and store up all the objects with which he has come into contact. Secondary defence against obsessional *affects* leads to a still wider set of protective measures which are capable of being transformed into obsessional acts. These may be grouped according to their purpose: *penitential* measures (burdensome ceremonials, the observation of numbers), *precautionary* measures (all sorts of phobias, superstition, pedantry, increase of the primary symptom of conscientiousness); measures to do with *fear of betrayal* (collecting scraps of paper, seclusiveness), or to ensure *numbing* (dipsomania). Among these obsessional acts and obsessional impulses, phobias, since they circumscribe the patient's existence, play the greatest part.

There are cases in which one can observe how the obsession is transferred from the idea or from the affect on to the protective measure; others in which the obsession oscillates periodically between the symptom of the return of the repressed and the symptom of the secondary defence; and yet other cases in which no obsessional idea is constructed at all, but, instead, the repressed memory is at once represented by what is apparently a primary measure of defence. Here we reach at one bound the stage which elsewhere only completes the course run by the obsessional neurosis after the defensive struggle has taken place. Severe cases of this disorder end in the ceremonial actions becoming fixated, or in a general state of doubting mania, or in a life of eccentricity conditioned by phobias.

The fact that the obsessional ideas and everything derived from them meet with no belief is no doubt because at their first repression the defensive symptom of *conscientiousness* has been formed and that that symptom, too, acquires an obsessional force. The subject's certainty of having lived a moral life throughout the whole period of his successful defence makes it impossible for him to believe the self-reproach which his obsessional idea involves. Only transitorily, too, on the appearance of a new obsessional idea and occasionally in melancholic states of exhaustion of the ego, do the pathological symptoms of the return of the repressed compel belief. The 'obsessional' character of the psychical formations which I have described here has quite generally nothing to do with attaching belief to them. Nor is it to be confused with the factor which is described as the 'strength' or 'intensity' of an idea. Its essence is rather indissolubility by psychical activity that is capable of being conscious; and this attribute undergoes no change, whether the idea to which the obsession attaches is stronger or weaker, or less or more intensely 'illuminated', or 'cathected with energy' and so on.

The cause of this invulnerability of the obsessional idea and its derivatives is, however, nothing more than its connection with the repressed memory from early childhood. For if we can succeed in making that connection conscious - and psychotherapeutic methods already appear able to do so - the obsession, too, is resolved.

III

ANALYSIS OF A CASE OF CHRONIC PARANOIA ¹

For a considerable time I have harboured a suspicion that paranoia, too - or classes of cases which fall under the heading of paranoia - is a psychosis of defence; that is to say, that, like hysteria and obsessions, it proceeds from the repression of distressing memories and that its symptoms are determined in their form by the content of what has been repressed. Paranoia must, however, have a special method or mechanism of repression which is peculiar to it, in the same way as hysteria effects repression by the method of conversion into somatic innervation, and obsessional neurosis by the method of *substitution* (viz. by displacement along the lines of certain categories of associations). I had observed several cases which favoured this interpretation, but had found none which proved it; until, a few months ago, I had an opportunity, through the kindness of Dr. Josef Breuer, of undertaking the psycho-analysis for therapeutic purposes of an intelligent woman of thirty-two, in whose case a diagnosis of chronic paranoia could not be questioned. I am reporting in these pages, without waiting further, some of the information I have been able to obtain from this piece of work, because I have no prospect of studying paranoia except in very isolated instances, and because I think it possible that my remarks may encourage a psychiatrist better placed than I am in this matter to give its rightful place to the factor of 'defence' in the discussion as to the nature and psychical mechanism of paranoia which is being carried on so actively just now. I have, of course, on the strength of the following single observation, no intention of saying more than: 'This case is a psychosis of defence and there are most probably others in the class of "paranoia" which are equally so.'

¹ (Footnote added 1924:) More correctly, no doubt, *dementia paranoides*.

Frau P., thirty-two years of age, has been married for three years and is the mother of a child of two. Her parents were not neurotic; but her brother and sister are to my knowledge, like her, neurotic. It is doubtful whether she may not, at one time in her middle twenties, have become temporarily depressed and confused in her judgement. In recent years she was healthy and capable, until, six months after the birth of her child, she showed the first signs of her present illness. She became uncommunicative and distrustful, showed aversion to meeting her husband's brothers and sisters and complained that the neighbours in the small town in which she lived were behaving differently towards her from how they did before and were rude and inconsiderate to her. By degrees these complaints increased in intensity, although not in definiteness. She thought people had something against her, though she had no idea what; but there was no doubt that everyone - relatives and friends - had ceased to respect her and were doing all they could to slight her. She had racked her brains, she said, to find the reason for this, but had no idea. A little time later she complained that she was being watched and that people were reading her thoughts and knew everything that was going on in her house. One afternoon she suddenly had the idea that she was being watched while she was undressing in the evening. From that time on she took the most precautionary measures when she undressed; she got into bed in the dark and did not begin to take off her things till she was under the bedclothes. Since she avoided all contact with other people, ate poorly and was very depressed, she was sent in the summer of 1895 to a hydropathic establishment. There, fresh symptoms appeared and those she already had increased in strength. Already in the spring of that year, when she was alone one day with her housemaid, she had suddenly had a sensation in her lower abdomen, and had thought to herself that the girl had at that moment had an improper idea. This sensation grew more frequent during the summer and became almost continual. She felt her genitals 'as one feels a heavy hand'. Then she began to see images which horrified her - hallucinations of naked women, especially of the lower part of a woman's abdomen with pubic hairs, and occasionally of male genitals as well. The image of the abdomen with hair and the physical sensation in her own abdomen usually occurred together. The images became very tormenting, for they happened regularly when she was in the company of a woman, and it made her think that she was seeing the woman in an indecent state of nakedness, but that simultaneously the woman was having the same picture of her (!). At the same time as these visual hallucinations - which vanished again for several months after their first appearance in the hydropathic establishment - she began to be pestered by voices which she did not recognize and which she could not account for. When she was in the street, they said: 'That's Frau P.- There she goes! Where's she going to?' Every one of her movements and actions was commented on; and at times she heard threats and reproaches. All these symptoms became worse when she was in company or in the street. For that reason she refused to go out; she said that eating disgusted her; and her state of health rapidly deteriorated.

I gathered all this from her when she came to Vienna for treatment with me in the winter of 1895. I have set it out at length because I want to convey the impression that what we are dealing with here really is a quite frequent form of chronic paranoia - a conclusion with which the details of her symptoms and behaviour which I have still to describe will be found to tally. At that time she concealed from me the delusions which served to interpret her hallucinations, or else the delusions had in fact not yet occurred to her. Her intelligence was undiminished; the only unusual thing I learnt was that she had repeatedly made appointments with her brother, who lived in the neighbourhood, in order to confide something important to him, but had never told him anything. She never spoke about her hallucinations, and towards the end she no longer said much either about the slights and persecutions of which she was subjected.

What I have to report about this patient concerns the aetiology of the case and the mechanism of the hallucinations. I discovered the aetiology when I applied Breuer's method, exactly as in a case of hysteria - in the first instance for the investigation and removal of the hallucinations. In doing so, I started out from the assumption that in this case of paranoia, just as in the two other defence neuroses with which I was familiar, there must be unconscious thoughts and repressed memories which could be brought into consciousness in the same way as they were in those neuroses, by overcoming a certain resistance. The patient at once confirmed my expectation, for she behaved in analysis exactly like, for instance, a hysterical patient; with her attention on the pressure of my hand,¹ she produced thoughts which she could not remember having had, which at first she did not understand and which were contrary to her expectations. The presence of significant unconscious ideas was thus demonstrated in a case of paranoia as well, and I was able to hope that I might trace the compulsion of paranoia, too, to repression. The only peculiarity was that the thoughts which arose from the unconscious were for the most part heard inwardly or hallucinated by the patient, in the same way as her voices.

¹ Cf. my *Studies on Hysteria*.

Concerning the origin of the visual hallucinations, or at least of the vivid images, I learned the following. The image of the lower part of a woman's abdomen almost always coincided with the physical sensation in her own abdomen; but the latter was much more constant and often occurred without the image. The first images of a woman's abdomen had appeared in the hydropathic establishment a few hours after she had in fact seen a number of naked women at the baths; so they turned out to be simple reproductions of a real impression. It was therefore to be presumed that these impressions had been repeated only because great interest was attached to them. She told me that she had felt ashamed for these women; she herself had been ashamed to be seen naked for as long as she could remember. Since I was obliged to regard the shame as something obsessional, I concluded, in accordance with the mechanism of defence, that an experience must have been repressed here about which she had *not* felt ashamed. So I requested her to let the memories emerge which belonged to the theme of feeling ashamed. She promptly reproduced a series of scenes going back from her seventeenth to her eighth year, in which she had felt ashamed of being naked in her bath in front of her mother, her sister and the doctor; but the series ended in a scene at the age of six, in which she was undressing in the nursery before going to bed, without feeling any shame in front of her brother who was there. On my questioning her, it transpired that scenes like this had occurred often and that the brother and sister had for years been in the habit of showing themselves to one another naked before going to bed. I now understood the meaning of her sudden idea that she was being watched as she was going to bed. It was an unaltered piece of the old memory which involved self-reproach, and she was now making up for the shame which she had omitted to feel as a child.

My conjecture that we had to do with an affair between children, as is so often found in the aetiology of hysteria, was strengthened by the further progress of the analysis, which at the same time yielded solutions of individual details that frequently recurred in the clinical picture of the paranoia. The patient's depression began at the time of a quarrel between her husband and her brother, as a result of which the latter no longer came to the house. She had always been very fond of this brother and she missed him very much at that time. Besides this she spoke of a certain moment in her illness at which for the first time 'everything became clear to her' - that is, at which she became convinced of the truth of her suspicion that she was despised by everyone and deliberately slighted. This certainty came to her during a visit from her sister-in-law who, in the course of conversation, let fall the words: 'If anything of that sort happens to me, I treat it in a light vein.' At first Frau P. took this remark unsuspectingly; but later, after the visitor had left, it seemed to her that the words had contained a reproach, as if *she* was in the habit of taking serious things lightly; and from that moment on she was certain that she was the victim of general slander. When I questioned her as to what made her feel justified in applying the words to herself, she answered that it was the tone of voice in which her sister-in-law had spoken that had (although, it is true, only subsequently) convinced her of it. This is a detail which is characteristic of paranoia. I now obliged her to remember what her sister-in-law had been saying *before* the remark she complained of, and it emerged that the sister-in-law had related how in her parents' home there had been all sorts of difficulties with her *brothers*, and had added the wise comment: 'In every family all sorts of things happen that one would like to draw a veil over. But if anything of the kind happens to *me*, I take it lightly.' Frau P. now had to admit that her depression was attached to the statements made by her sister-in-law *before* her last remark. Since she had repressed both the statements which might have awakened a memory of her relations with her brother, and had only retained the insignificant last one, it was with it that she was obliged to connect her feeling that her sister-in-law was making a reproach against her; and since its *content* offered no basis for this, she turned from the content to the *tone* in which the words had been spoken. This is probably a typical piece of evidence that the misinterpretations of paranoia are based on a repression.

My patient's singular conduct, too, in making appointments with her brother, and then having nothing to tell him, was solved in a surprising fashion. Her explanation was that she had thought that if she could only look at him he would be bound to understand her sufferings, since he knew the cause of them. Now, as this brother was in fact the only person who could know about the aetiology of her illness, it was clear that she had been acting in accordance with a motive which, although she herself did not understand it consciously, could be seen to be perfectly justified as soon as it was supplied with a meaning derived from the unconscious.

I then succeeded in getting her to reproduce the various scenes in which her sexual relationship with her brother (which had certainly lasted at least from her sixth to her tenth year) had culminated. During this work of reproduction, the physical sensation in her abdomen 'joined in the conversation' as it were, as is regularly observed to happen in the analysis of hysterical mnemonic residues. The image of the lower part of a woman's naked abdomen (but now reduced to childish proportions and without hair on it) appeared with the sensation or stayed away, according as the scene in question had occurred in full light or in the dark. Her disgust at eating, too, found an explanation in a repulsive detail of these proceedings. After we had gone through this series of scenes, the hallucinatory sensations and images had disappeared, and (up to the present, at any rate) they have not returned.¹

¹ Later on, when an exacerbation of her illness undid the successful results of the treatment - which were in any case meagre - the patient no longer saw the offensive images of other people's genitals but had the idea that other people saw *her* genitals whenever they were *behind* her.

(Added 1922) The fragmentary account of this analysis in the text above was written while the patient was still undergoing treatment. Very shortly after, her condition became so much more serious that the treatment had to be broken off. She was transferred to an institution and there went through a period of severe hallucinations which had all the signs of dementia praecox. Contrary to expectation, however, she recovered and returned home, had another child which was quite healthy, and was able for a long period (12 to 15 years) to carry out all her duties in a satisfactory manner. The only sign of her earlier psychosis was said to be that she avoided the company of all relatives, whether of her own family or of her husband's. At the end of this period, affected by very adverse changes in her circumstances, she again became ill. Her husband had become unable to work and the relatives she had avoided were obliged to support the family. She was again sent to an institution, and died there soon after, of a pneumonia which rapidly supervened.

I had found, therefore, that these hallucinations were nothing else than parts of the content of repressed childhood experiences, symptoms of the return of the repressed.

I now turned to the analysis of the voices. First and foremost what had to be explained was why such an indifferent content as 'Here comes Frau P.', 'She's looking for a house now', and so on, could have been so distressing to her; next, how it was that precisely these innocent phrases had managed to be marked out by hallucinatory reinforcement. From the first it was clear that the 'voices' could not be *memories* that were being produced in a hallucinatory way, like the images and sensations, but were rather *thoughts* that were being 'said aloud'.

The first time she heard the voices was in the following circumstances. She had been reading Otto Ludwig's fine story, *Die Heiterethei*, with eager interest, and she noticed that while she was reading, thoughts were emerging which claimed her attention. Immediately afterwards, she went for a walk along a country road, and, as she was passing a small peasant's house, the voices suddenly said to her 'That's what the Heiterethei's cottage looked like! There's the spring and there are the bushes! How happy she was in spite of all her poverty!' The voices then repeated to her whole paragraphs from what she had just been reading. But it remained unintelligible why the Heiterethei's cottage and bushes and spring, and precisely the most trivial and irrelevant passages of the story, should be forced on her attention with pathological strength. However, the solution of the puzzle was not difficult. Her analysis showed that while she was reading, she had had other thoughts as well and that she had been excited by quite different passages in the book. Against this material - analogies between the couple in the story and herself and her husband, memories of intimacies in her married life, and of family secrets - against all this a repressing resistance had arisen because it was connected, by easily demonstrable trains of thought, with her aversion to sexuality and thus ultimately went back to the awakening of her old childhood experience. In consequence of this censorship exercised by the repression, the innocuous and idyllic passages, which were connected with the proscribed ones by contrast and also by propinquity, acquired the additional strength in their relation to consciousness which made it possible for them to be spoken aloud. The first of the repressed ideas, for instance, related to the slander to which the heroine, who lived alone, was exposed from her neighbours. My patient easily discovered the analogy with her own self. She, too, lived in a small place, met no one, and thought she was despised by her neighbours. This distrust of her neighbours had a real foundation. She had been obliged at first to be content with a small apartment, and the bedroom wall against which the young couple's double bed stood adjoined a room belonging to their neighbours. With the beginning of her marriage - obviously through an unconscious awakening of her childhood affair, in which she and her brother had played at husband and wife - she had developed a great aversion to sexuality. She was constantly worried in case her neighbours might hear words and noises through the party wall, and this shame turned into suspiciousness towards the neighbours.

Thus the voices owed their origin to the repression of thoughts which, in the last analysis, were in fact self-reproaches about experiences that were analogous to her childhood trauma. The voices were accordingly symptoms of the return of the repressed. But they were at the same time consequences of a compromise between the resistance of the ego and the power of the returning repressed - a compromise which in this instance had brought about a distortion that went beyond recognition. In other instances in which I had occasion to analyse Frau P.'s voices, the distortion was less great. Nevertheless, the words she heard always had a quality of diplomatic indefiniteness: the insulting allusion was generally deeply hidden; the connection between the separate sentences was disguised by a strange mode of expression, unusual forms of speech and so on - characteristics which are common to the auditory hallucinations of paranoics in general and in which I see the traces of distortion through compromise. For instance, the remark, 'there goes Frau P.; she's looking for a house in the street', meant a threat that she would never recover; for I had promised her that after her treatment she would be able to go back to the small town in which her husband worked. (She had provisionally taken rooms in Vienna for a few months.)

In isolated instances Frau P. also received more definite threats - for example, in regard to her husband's relatives; yet there was still a contrast between the reserved manner in which they were expressed and the torment which the voices caused her. In view of what is known of paranoia apart from this, I am inclined to suppose that there is a gradual impairment of the resistances which weaken the self-reproaches; so that finally the defence fails altogether and the original self-reproach, the actual term of abuse, from which the subject was trying to spare himself, returns in its unaltered form. I do not know, however, whether this course of events is a constant one, or whether the censorship of the words involving the self-reproach may be absent from the beginning or may persist to the end.

It only remains for me now to employ what has been learned from this case of paranoia for making a comparison between paranoia and obsessional neurosis. In each of them, repression has been shown to be the nucleus of the psychological mechanism, and in each what has been repressed is a sexual experience in childhood. In this case of paranoia, too, every obsession sprang from repression; the symptoms of paranoia allow of a classification similar to the one which has proved justified for obsessional neurosis. Part of the symptoms, once again, arise from primary defence - namely, all the delusional ideas which are characterized by distrust and suspicion and which are concerned with ideas of being persecuted by others. In obsessional neurosis the initial self-reproach has been repressed by the formation of the primary symptom of defence: *self-distrust*. With this, the self-reproach is acknowledged as justified; and, to weigh against this, the conscientiousness which the subject has acquired during his healthy interval now protects him from giving credence to the self-reproaches which return in the form of obsessional ideas. In paranoia, the self-reproach is repressed in a manner which may be described as *projection*. It is repressed by erecting the defensive symptom of *distrust of other people*. In this way the subject withdraws his acknowledgement of the self-reproach; and, as if to make up for this, he is deprived of a protection against the self-reproaches which return in his delusional ideas.

Other symptoms of my case of paranoia are to be described as symptoms of the return of the repressed, and they, too, like those of obsessional neurosis, bear the traces of the compromise which alone allows them to enter consciousness. Such are, for instance, my patient's delusional idea of being watched while she was undressing, her visual hallucinations, her hallucinations of sensation and her hearing of voices. In the delusional idea which I have just mentioned there is a mnemonic content which is almost unaltered and has only been made indefinite through omission. The return of the repressed in visual images approaches the character of hysteria rather than of obsessional neurosis; but hysteria is in the habit of repeating its mnemonic symbols without modification, whereas mnemonic hallucinations in paranoia undergo a distortion similar to that in obsessional neurosis: an analogous modern image takes the place of the repressed one. (E. g., the abdomen of an adult woman appears instead of a child's, and an abdomen on which the hairs are especially distinct, because they were absent in the original impression.) A thing which is quite peculiar to paranoia and on which no further light can be shed by this comparison, is that the repressed self-reproaches return in the form of thoughts spoken aloud. In the course of this process, they are obliged to submit to twofold distortion: they are subjected to a censorship, which leads to their being replaced by other, associated, thoughts or to their being concealed by an indefinite mode of expression, and they are referred to recent experiences which are no more than analogous to the old ones.

The third group of symptoms that are found in obsessional neurosis, the symptoms of secondary defence, cannot be present as such in paranoia, because no defence can avail against the returning symptoms to which, as we know, belief is attached. In place of this, we find in paranoia another source for the formation of symptoms. The delusional ideas which have arrived in consciousness by means of a compromise (the symptoms of the return) make demands on the thought-activity of the ego until they can be accepted without contradiction. Since they are not themselves open to influence, the ego must adapt itself to them; and thus what corresponds here to the symptoms of secondary defence in obsessional neurosis is a combinatory delusional formation - *interpretative delusions* which end in an *alteration of the ego*. In this respect, the case under discussion was not complete; at that time my patient did not as yet exhibit any signs of the attempts at interpretation which appeared later. But I have no doubt that if we apply psycho-analysis to this stage of paranoia as well, we shall be able to arrive at a further important result. It should then turn out that the so-called *weakness of memory* of paranoics is also a tendentious one - that is to say, that it is based on repression and serves the ends of repression. A subsequent repression and replacement takes place of memories which are not in the least pathogenic, but which are in contradiction to the alteration of the ego which the symptoms of the return of the repressed so insistently demand.

THE AETIOLOGY OF HYSTERIA
(1896)

Intentionally left blank

THE AETIOLOGY OF HYSTERIA

GENTLEMEN, - When we set out to form an opinion about the causation of a pathological state such as hysteria, we begin by adopting the method of anamnestic investigation: we question the patient or those about him in order to find out to what harmful influences they themselves attribute his having fallen ill and developed these neurotic symptoms. What we discover in this way is, of course, falsified by all the factors which commonly hide the knowledge of his own state from a patient - by his lack of scientific understanding of aetiological influences, by the fallacy of *post hoc, propter hoc*, by his reluctance to think about or mention certain noxae and traumas. Thus in making an anamnestic investigation of this sort, we keep to the principle of not adopting the patients' belief without a thorough critical examination, of not allowing them to lay down our scientific opinion for us on the aetiology of the neurosis. Although we do, on the one hand, acknowledge the truth of certain constantly repeated assertions, such as that the hysterical state is a long-persisting after-effect of an emotion experienced in the past, we have, on the other hand, introduced into the aetiology of hysteria a factor which the patient himself never brings forward and whose validity he only reluctantly admits - namely, the hereditary disposition derived from his progenitors. As you know, in the view of the influential school of Charcot heredity alone deserves to be recognized as the true cause of hysteria, while all other noxae of the most various nature and intensity only play the part of incidental causes, of '*agents provocateurs*'.

You will readily admit that it would be a good thing to have a second method of arriving at the aetiology of hysteria, one in which we should feel less dependent on the assertions of the patients themselves. A dermatologist, for instance, is able to recognize a sore as luetic from the character of its margins, or the crust on it and of its shape, without being misled by the protestations of his patient, who denies any source of infection for it; and a forensic physician can arrive at the cause of an injury, even if he has to do without any information from the injured person. In hysteria, too, there exists a similar possibility of penetrating from the symptoms to a knowledge of their causes. But in order to explain the relationship between the method which we have to employ for this purpose and the older method of anamnestic enquiry, I should like to bring before you an analogy taken from an advance that has in fact been made in another field of work.

Imagine that an explorer arrives in a little-known region where his interest is aroused by an expanse of ruins, with remains of walls, fragments of columns, and tablets with half effaced and unreadable inscriptions. He may content himself with inspecting what lies exposed to view, with questioning the inhabitants - perhaps semi-barbaric people - who live in the vicinity, about what tradition tells them of the history and meaning of these archaeological remains, and with noting down what they tell him - and he may then proceed on his journey. But he may act differently. He may have brought picks, shovels and spades with him, and he may set the inhabitants to work with these implements. Together with them he may start upon the ruins, clear away the rubbish, and, beginning from the visible remains, uncover what is buried. If his work is crowned with success, the discoveries are self-explanatory; the ruined walls are part of the ramparts of a palace or a treasure house; the fragments of columns can be filled out into a temple; the numerous inscriptions, which, by good luck, may be bilingual, reveal an alphabet and a language, and, when they have been deciphered and translated, yield undreamed-of information about the events of the remote past, to commemorate which the monuments were built. *Saxa loquuntur!*

If we try, in an approximately similar way, to induce the symptoms of a hysteria to make themselves heard as witnesses to the history of the origin of the illness, we must take our start from Josef Breuer's momentous discovery: *the symptoms of hysteria (apart from the stigmata) are determined by certain experiences of the patient's which have operated in a traumatic fashion and which are being reproduced in his psychical life in the form of mnemonic symbols*. What we have to do is to apply Breuer's method - or one which is essentially the same - so as to lead the patient's attention back from his symptom to the scene in which and through which that symptom arose; and, having thus located the scene, we remove the symptom by bringing about, during the reproduction of the traumatic scene, a subsequent correction of the psychical course of events which took place at the time.

It is no part of my intention to-day to discuss the difficult technique of this therapeutic procedure or the psychological discoveries which have been obtained by its means. I have been obliged to start from this point only because the analyses conducted on Breuer's lines seem at the same time to open up the path to the causes of hysteria. If we subject a fairly large number of symptoms in a great number of subjects to such an analysis, we shall, of course, arrive at a knowledge of a correspondingly large number of traumatically operative scenes. It was in these experiences that the efficient causes of hysteria came into action. Hence we may hope to discover from the study of these traumatic scenes what the influences are which produce hysterical symptoms and in what way they do so.

This expectation proves true; and it cannot fail to, since Breuer's theses, when put to the test in a considerable number of cases, have turned out to be correct. But the path from the symptoms of hysteria to its aetiology is far more laborious and leads through other connections than one would have imagined.

For let us be clear on this point. Tracing a hysterical symptom back to a traumatic scene assists our understanding only if the scene satisfies two conditions; if it possesses the relevant *suitability to serve as a determinant* and if it recognizably possesses the necessary *traumatic force*. Instead of a verbal explanation, here is an example. Let us suppose that the symptom under consideration is hysterical vomiting; in that case we shall feel that we have been able to understand its causation (except for a certain residue) if the analysis traces the symptom back to an experience which *justifiably produced a high amount of disgust* - for instance, the sight of a decomposing dead body. But if, instead of this, the analysis shows us that the vomiting arose from a great fright, e.g. from a railway accident, we shall feel dissatisfied and will have to ask ourselves how it is that the fright has led to the particular symptom of vomiting. This derivation lacks *suitability as a determinant*. We shall have another instance of an insufficient explanation if the vomiting is supposed to have arisen from, let us say, eating a fruit which had partly gone bad. Here, it is true, the vomiting *is* determined by disgust, but we cannot understand how, in this instance, the disgust could have become so powerful as to be perpetuated in a hysterical symptom; the experience lacks *traumatic force*.

Let us now consider how far the traumatic scenes of hysteria which are uncovered by analysis fulfil, in a fairly large number of symptoms and cases, the two requirements which I have named. Here we meet with our first great disappointment. It is true, indeed, that the traumatic scene in which the symptom originated does in fact occasionally possess both the qualities - suitability as a determinant and traumatic force - which we require for an understanding of the symptom. But far more frequently, incomparably more frequently, we find one of the three other possibilities realized, which are so unfavourable to an understanding. Either the scene to which we are led by analysis and in which the symptom first appeared seems to us unsuited for determining the symptom, in that its content bears no relation to the nature of the symptom; or the allegedly traumatic experience, though it does have a relation to the symptom, proves to be an impression which is normally innocuous and incapable as a rule of producing any effect; or, lastly, the 'traumatic scene' leaves us in the lurch in both respects, appearing at once innocuous and unrelated to the character of the hysterical symptom.

(Here I may remark in passing that Breuer's view of the origin of hysterical symptoms is not shaken by the discovery of traumatic scenes which correspond to experiences that are insignificant in themselves. For Breuer assumed - following Charcot - that even an innocuous experience can be heightened into a trauma and can develop determining force if it happens to the subject when he is in a special psychical condition - in what is described as a *hypnoid state*. I find, however, that there are often no grounds whatever for presupposing the presence of such hypnoid states. What remains decisive is that the theory of hypnoid states contributes nothing to the solution of the other difficulties, namely that the traumatic scenes so often lack suitability as determinants.)

Moreover, Gentlemen, this first disappointment we meet with in following Breuer's method is immediately succeeded by another, and one that must be especially painful to us as physicians. When our procedure leads, as in the cases described above, to findings which are insufficient as an explanation both in respect to their suitability as determinants and to their traumatic effectiveness, we also fail to secure any therapeutic gain; the patient retains his symptoms unaltered, in spite of the initial result yielded by the analysis. You can understand how great the temptation is at this point to proceed no further with what is in any case a laborious piece of work.

But perhaps all we need is a new idea in order to help us out of our dilemma and lead to valuable results. The idea is this. As we know from Breuer, hysterical symptoms can be resolved if, starting from them, we are able to find the path back to the memory of a traumatic experience. If the memory which we have uncovered does not answer our expectations, it may be that we ought to pursue the same path a little further; perhaps behind the first traumatic scene there may be concealed the memory of a second, which satisfies our requirements better and whose reproduction has a greater therapeutic effect; so that the scene that was first discovered only has the significance of a connecting link in the chain of associations. And perhaps this situation may repeat itself; inoperative scenes may be interpolated more than once, as necessary transitions in the process of reproduction, until we finally make our way from the hysterical symptom to the scene which is really operative traumatically and which is satisfactory in every respect, both therapeutically and analytically. Well, Gentlemen, this supposition is correct. If the first-discovered scene is unsatisfactory, we tell our patient that this experience explains nothing, but that behind it there must be hidden a more significant, earlier, experience; and we direct his attention by the same technique to the associative thread which connects the two memories - the one that has been discovered and the one that has still to be discovered.¹ A continuation of the analysis then leads in every instance to the reproduction of new scenes of the character we expect. For example, let us take once again the case of hysterical vomiting which I selected before, and in which the analysis first led back to a fright from a railway accident - a scene which lacked suitability as a determinant. Further analysis showed that this accident had aroused in the patient the memory of another, earlier accident, which, it is true, he had not himself experienced but which had been the occasion of his having a ghastly and revolting sight of a dead body. It is as though the combined operation of the two scenes made the fulfilment of our postulates possible, the one experience supplying, through fright, the traumatic force and the other, from its content, the determining effect. The other case, in which the vomiting was traced back to eating an apple which had partly gone bad, was amplified by the analysis somewhat in the following way. The bad apple reminded the patient of an earlier experience: while he was picking up windfalls in an orchard he had accidentally come upon a dead animal in a revolting state.

I shall not return any further to these examples, for I have to confess that they are not derived from any case in my experience but are inventions of mine. Most probably, too, they are bad inventions. I even regard such solutions of hysterical symptoms as impossible. But I was obliged to make up fictitious examples for several reasons, one of which I can state at once. The real examples are all incomparably more complicated: to relate a single one of them in detail would occupy the whole period of this lecture. The chain of associations always has more than two links; and the traumatic scenes do not form a simple row, like a string of pearls, but ramify and are interconnected like genealogical trees, so that in any new experience two or more earlier ones come into operation as memories. In short, giving an account of the resolution of a single symptom would in fact amount to the task of relating an entire case history.

¹ I purposely leave out of this discussion the question of what the category is to which the association between the two memories belong, (whether it is an association by simultaneity, or by causal connections or by similarity of content), and of what psychological character is to be attributed to the various 'memories' (conscious or unconscious).

But we must not fail to lay special emphasis on one conclusion to which analytic work along these chains of memory has unexpectedly led. We have learned that *no hysterical experience can arise from a real experience alone, but that in every case the memory of earlier experiences awakened in association to it plays a part in causing the symptom*. If - as I believe - this proposition holds good *without exception*, it furthermore shows us the basis on which a psychological theory of hysteria must be built.

You might suppose that the rare instances in which analysis is able to trace the symptom back direct to a traumatic scene that is thoroughly suitable as a determinant and possesses traumatic force, and is able, by thus tracing it back, at the same time to remove it (in the way described in Breuer's case history of Anna O.) - you might suppose that such instances must, after all, constitute powerful objections to the general validity of the proposition I have just put forward. It certainly looks so. But I must assure you that I have the best grounds for assuming that even in such instances there exists a chain of operative memories which stretches far back behind the first traumatic scene, *even though* the reproduction of the latter alone may have the result of removing the symptom.

It seems to me really astonishing that hysterical symptoms can only arise with the co-operation of memories, especially when we reflect that, according to the unanimous accounts of the patients themselves, these memories did not come into their consciousness at the moment when the symptom first made its appearance. Here is much food for thought; but these problems must not distract us at this point from our discussion of the aetiology of hysteria. We must rather ask ourselves: where shall we get to if we follow the chains of associated memories which the analysis has uncovered? How far do they extend! Do they come anywhere to a natural end? Do they perhaps lead to experiences which are in some way alike, either in their content or the time of life at which they occur, so that we may discern in these universally similar factors the aetiology of hysteria of which we are in search?

The knowledge I have so far gained already enables me to answer these questions. If we take a case which presents several symptoms, we arrive by means of the analysis, starting from each symptom, at a series of experiences the memories of which are linked together in association. To begin with, the chains of memories lead backwards separately from one another; but, as I have said, they ramify. From a single scene two or more memories are reached at the same time, and from these again side-chains proceed whose individual links may once more be associatively connected with links belonging to the main chain. Indeed, a comparison with the genealogical tree of a family whose members have also intermarried, is not at all a bad one. Other complications in the linkage of the chains arise from the circumstance that a single scene may be called up several times in the same chain, so that it has multiple relationships to a later scene, and exhibits both a direct connection with it and a connection established through intermediate links. In short, the concatenation is far from being a simple one; and the fact that the scenes are uncovered in a reversed chronological order (a fact which justifies our comparison of the work with the excavation of a stratified ruined site) certainly contributes nothing to a more rapid understanding of what has taken place.

If the analysis is carried further, new complications arise. The associative chains belonging to the different symptoms begin to enter into relation with one another; the genealogical trees become intertwined. Thus a particular symptom in, for instance, the chain of memories relating to the symptom of vomiting, calls up not only the earlier links in its own chain but also a memory from another chain, relating to another symptom, such as a headache. This experience accordingly belongs to both series, and in this way it constitutes a *nodal point*. Several such nodal points are to be found in every analysis. Their correlate in the clinical picture may perhaps be that from a certain time onwards both symptoms have appeared together, symbiotically, without in fact having any internal dependence on each other. Going still further back, we come upon nodal points of a different kind. Here the separate associative chains converge. We find experiences from which two or more symptoms have proceeded; one chain has attached itself to one detail of the scene, the second chain to another detail.

But the most important finding that is arrived at if an analysis is thus consistently pursued is this. Whatever case and whatever symptom we take as our point of departure, *in the end we infallibly come to the field of sexual experience*. So here for the first time we seem to have discovered an aetiological precondition.

From previous experience I can foresee that it is precisely against this assertion or against its universal validity that your contradiction, Gentlemen, will be directed. Perhaps it would be better to say, your *inclination* to contradict; for none of you, no doubt, have as yet any investigations at your disposal which, based upon the same procedure, might have yielded a different result. As regards the controversial matter itself, I will only remark that the singling out of the sexual factor in the aetiology of hysteria springs at least from no preconceived opinion of my part. The two investigators as whose pupil I began my studies of hysteria, Charcot and Breuer, were far from having any such presupposition; in fact they had a personal disinclination to it which I originally shared. Only the most laborious and detailed investigations have converted me, and that slowly enough, to the view I hold to-day. If you submit my assertion that the aetiology of hysteria lies in sexual life to the strictest examination, you will find that it is supported by the fact that in some eighteen cases of hysteria I have been able to discover this connection in every single symptom, and, where the circumstances allowed, to confirm it by therapeutic success. No doubt you may raise the objection that the nineteenth or the twentieth analysis will perhaps show that hysterical symptoms are derived from other sources as well, and thus reduce the universal validity of the sexual aetiology to one of eighty percent. By all means let us wait and see; but, since these eighteen cases are at the same time *all* the cases on which I have been able to carry out the work of analysis and since they were not picked out by anyone for my convenience, you will find it understandable that I do not share such an expectation but am prepared to let my belief run ahead of the evidential force of the observations I have so far made. Besides, I am influenced by another motive as well, which for the moment is of merely subjective value. In the sole attempt to explain the physiological and psychical mechanism of hysteria which I have been able to make in order to correlate my observations, I have come to regard the participation of sexual motive forces as an indispensable premiss.

Eventually, then, after the chains of memories have converged, we come to the field of sexuality and to a small number of experiences which occur for the most part at the same period of life - namely, at puberty. It is in these experiences, it seems, that we are to look for the aetiology of hysteria, and through them that we are to learn to understand the origin of hysterical symptoms. But here we meet with a fresh disappointment and a very serious one. It is true that these experiences, which have been discovered with so much trouble and extracted out of all the mnemonic material, and which seemed to be the ultimate traumatic experiences, have in common the two characteristics of being sexual and of occurring at puberty; but in every other respect they are very different from each other both in *kind* and in *importance*. In some cases, no doubt, we are concerned with experiences which must be regarded as severe traumas - an attempted rape, perhaps, which reveals to the immature girl at a blow all the brutality of sexual desire, or the involuntary witnessing of sexual acts between parents, which at one and the same time uncovers unsuspected ugliness and wounds childish and moral sensibilities alike, and so on. But in other cases the experiences are astonishingly trivial. In one of my women patients it turned out that her neurosis was based on the experience of a boy of her acquaintance stroking her hand tenderly and, at another time, pressing his knee against her dress as they sat side by side at table, while his expression let her see that he was doing something forbidden. For another young lady, simply hearing a riddle which suggested an obscene answer had been enough to provoke the first anxiety attack and with it to start the illness. Such findings are clearly not favourable to an understanding of the causation of hysterical symptoms. If serious and trifling events alike, and if not only experiences affecting the subject's own body but visual impressions too and information received through the ears are to be recognized as the ultimate traumas of hysteria, then we may be tempted to hazard the explanation that hysterics are peculiarly constituted creatures - probably on account of some hereditary disposition or degenerative atrophy - in whom a shrinking from sexuality, which normally plays some part at puberty, is raised to a pathological pitch and is permanently retained; that they are, as it were, people who are psychically inadequate to meeting the demands of sexuality. This view, of course, leaves hysteria in men out of account. But even without blatant objections such as that, we should scarcely be tempted to be satisfied with this solution. We are only too distinctly conscious of an intellectual sense of something half-understood, unclear and insufficient.

Luckily for our explanation, some of these sexual experiences at puberty exhibit a further inadequacy, which is calculated to stimulate us into continuing our analytic work. For it sometimes happens that they, too, lack suitability as determinants although this is much more rarely so than with the traumatic scenes belonging to later life. Thus, for instance, let us take the two women patients whom I have just spoken of as cases in which the experiences at puberty were actually innocent ones. As a result of those experiences the patients had become subject to peculiar painful sensations in the genitals which had established themselves as the main symptoms of the neurosis. I was unable to find indications that they had been determined either by the scenes at puberty or by later scenes; but they were certainly not normal organic sensations nor signs of sexual excitement. It seemed an obvious thing, then, to say to ourselves that we must look for the determinants of these symptoms in yet other experiences, in experiences which went still further back - and that we must, for the second time, follow the saving notion which had earlier led us from the first traumatic scenes to the chains of memories behind them. In doing so, to be sure, we arrive at the period of earliest childhood, a period before the development of sexual life; and this would seem to involve the abandonment of a sexual aetiology. But have we not a right to assume that even the age of childhood is not wanting in slight sexual excitations, that later sexual development may perhaps be decisively influenced by childhood experiences? Injuries sustained by an organ which is as yet immature, or by a function which is in process of developing, often cause more severe and lasting effects than they could do in maturer years. Perhaps the abnormal reaction to sexual impressions which surprises us in hysterical subjects at the age of puberty is quite generally based on sexual experiences of this sort in childhood, in which case those experiences must be of a similar nature to one another, and must be of an important kind. If this is so, the prospect is opened up that what has hitherto had to be laid at the door of a still unexplained hereditary predisposition may be accounted for as having been acquired at an early age. And since infantile experiences with a sexual content could after all only exert a psychical effect through their *memory-traces*, would not this view be a welcome amplification of the finding of psycho-analysis which tells us that *hysterical symptoms can only arise with the co-operation of memories?*

II

You will no doubt have guessed, Gentlemen, that I should not have carried this last line of thought so far if I had not wanted to prepare you for the idea that it is this line alone which, after so many delays, will lead us to our goal. For now we are really at the end of our wearisome and laborious analytic work, and here we find the fulfilment of all the claims and expectations upon which we have so far insisted. If we have the perseverance to press on with the analysis into early childhood, as far back as a human memory is capable of reaching, we invariably bring the patient to reproduce experiences which, on account both of their peculiar features and of their relations to the symptoms of his later illness, must be regarded as the aetiology of his neurosis for which we have been looking. These *infantile* experiences are once more *sexual* in content, but they are of a far more uniform kind than the scenes at puberty that had been discovered earlier. It is now no longer a question of sexual topics having been aroused by some sense impression or other, but of sexual experiences affecting the subject's own body - of *sexual intercourse* (in the wider sense). You will admit that the *importance* of such scenes needs no further proof; to this may now be added that, in every instance, you will be able to discover in the details of the scenes the *determining* factors which you may have found lacking in the other scenes - the scenes which occurred later and were reproduced earlier.

I therefore put forward the thesis that at the bottom of every case of hysteria there are *one or more occurrences of premature sexual experience*, occurrences which belong to the earliest years of childhood but which can be reproduced through the work of psycho-analysis in spite of the intervening decades. I believe that this is an important finding, the discovery of a *caput Nili* in neuropathology; but I hardly know what to take as a starting-point for a continuation of my discussion of this subject. Shall I put before you the actual material I have obtained from my analyses? Or shall I rather try first to meet the mass of objections and doubts which, as I am surely correct in supposing, have now taken possession of your attention? I shall choose the latter course; perhaps we shall then be able to go over the facts more calmly.

(a) No one who is altogether opposed to a psychological view of hysteria, who is unwilling to give up the hope that some day it will be possible to trace back its symptoms to 'finer anatomical changes' and who has rejected the view that the material foundations of hysterical changes are bound to be of the same kind as those of our normal mental processes - no one who adopts this attitude will, of course, put any faith in the results of our analyses; however, the difference in principle between his premisses and ours absolves us from the obligation of convincing him on individual points.

But other people, too, although they may be less averse to psychological theories of hysteria, will be tempted, when considering our analytic findings, to ask what degree of certainty the application of psycho-analysis offers. Is it not very possible either that the physician forces such scenes upon his docile patients, alleging that they are memories, or else that the patients tell the physician things which they have deliberately invented or have imagined and that he accepts those things as true? Well, my answer to this is that the general doubt about the reliability of the psycho-analytic method can be appraised and removed only when a complete presentation of its technique and results is available. Doubts about the genuineness of the infantile sexual scenes can, however, be deprived of their force here and now by more than one argument. In the first place, the behaviour of patients while they are reproducing these infantile experiences is in every respect incompatible with the assumption that the scenes are anything else than a reality which is being felt with distress and reproduced with the greatest reluctance. Before they come for analysis the patients know nothing about these scenes. They are indignant as a rule if we warn them that such scenes are going to emerge. Only the strongest compulsion of the treatment can induce them to embark on a reproduction of them. While they are recalling these infantile experiences to consciousness, they suffer under the most violent sensations, of which they are ashamed and which they try to conceal; and, even after they have gone through them once more in such a convincing manner, they still attempt to withhold belief from them, by emphasizing the fact that, unlike what happens in the case of other forgotten material, they have no feeling of remembering the scenes.¹

This latter piece of behaviour seems to provide conclusive proof. Why should patients assure me so emphatically of their unbelief, if what they want to discredit is something which - from whatever motive - they themselves have invented?

It is less easy to refute the idea that the doctor forces reminiscences of this sort on the patient, that he influences him by suggestion to imagine and reproduce them. Nevertheless it appears to me equally untenable. I have never yet succeeded in forcing on a patient a scene I was expecting to find, in such a way that he seemed to be living through it with all the appropriate feelings. Perhaps others may be more successful in this.

¹ (Footnote added 1924:) All this is true; but it must be remembered that at the time I wrote it I had not yet freed myself from my *overvaluation* of reality and my *low valuation* of phantasy.

There are, however, a whole number of other things that vouch for the reality of infantile sexual scenes. In the first place there is the uniformity which they exhibit in certain details, which is a necessary consequence if the preconditions of these experiences are always of the same kind, but which would otherwise lead us to believe that there were secret understandings between the various patients. In the second place, patients sometimes describe as harmless events whose significance they obviously do not understand, since they would be bound otherwise to be horrified by them. Or again, they mention details, without laying any stress on them, which only someone of experience in life can understand and appreciate as subtle traits of reality.

Events of this sort strengthen our impression that the patients must really have experienced what they reproduce under the compulsion of analysis as scenes from their childhood. But another and stronger proof of this is furnished by the relationship of the infantile scenes to the content of the whole of the rest of the case history. It is exactly like putting together a child's picture-puzzle: after many attempts, we become absolutely certain in the end which piece belongs in the empty gap; for only that one piece fills out the picture and at the same time allows its irregular edges to be fitted into the edges of the other pieces in such a manner as to leave no free space and to entail no overlapping. In the same way, the contents of the infantile scenes turn out to be indispensable supplements to the associative and logical framework of the neurosis, whose insertion makes its course of development for the first time evident, or even, as we might often say, self-evident.

Without wishing to lay special stress on the point, I will add that in a number of cases therapeutic evidence of the genuineness of the infantile scenes can also be brought forward. There are cases in which a complete or partial cure can be obtained without our having to go as deep as the infantile experiences. And there are others in which no success at all is obtained until the analysis has come to its natural end with the uncovering of the earliest traumas. In the former cases we are not, I believe, secure against relapses; and my expectation is that a complete psycho-analysis implies a radical cure of the hysteria. We must not, however, be led into forestalling the lessons of observation.

There would be one other proof, and a really unassailable one, of the genuineness of childhood sexual experiences namely, if the statements of someone who is being analysed were to be confirmed by someone else, whether under treatment or not. These two people will have had to have taken part in the same experience in their childhood - perhaps to have stood in some sexual relationship to each other. Such relations between children are, as you will hear in a moment, by no means rare. Moreover, it quite often happens that both of those concerned subsequently fall ill of neuroses; yet I regard it as a fortunate accident that, out of eighteen cases, I have been able to obtain an objective confirmation of this sort in two. In one instance, it was the brother (who had remained well) who of his own accord confirmed - not, it is true, his earliest sexual experiences with his sister (who was the patient) - but at least scenes of that kind from later childhood, and the fact that there had been sexual relations dating further back. In the other instance, it happened that two women whom I was treating had as children had sexual relations with the same man, in the course of which certain scenes had taken place *à trois*. A particular symptom, which was derived from these childhood events, had developed in both women, as evidence of what they had experienced in common.

(b) Sexual experiences in childhood consisting in stimulation of the genitals, coitus-like acts, and so on, must therefore be recognized, in the last analysis, as being the traumas which lead to a hysterical reaction to events at puberty and to the development of hysterical symptoms. This statement is certain to be met from different directions by two mutually contradictory objections. Some people will say that sexual abuses of this kind, whether practised upon children or between them, happen too seldom for it to be possible to regard them as the determinant of such a common neurosis as hysteria. Others will perhaps argue that, on the contrary, such experiences are very frequent - much too frequent for us to be able to attribute an aetiological significance to the fact of their occurrence. They will further maintain that it is easy, by making a few enquiries, to find people who remember scenes of sexual seduction and sexual abuse in their childhood years, and yet who have never been hysterical. Finally we shall be told, as a weighty argument, that in the lower strata of the population hysteria is certainly no more common than in the highest ones, whereas everything goes to show that the injunction for the sexual safeguarding of childhood is far more frequently transgressed in the case of the children of the proletariat.

Let us begin our defence with the easier part of the task. It seems to me certain that our children are far more often exposed to sexual assaults than the few precautions taken by parents in this connection would lead us to expect. When I first made enquiries about what was known on the subject, I learnt from colleagues that there are several publications by paediatricians which stigmatize the frequency of sexual practices by nurses and nursery maids, carried out even on infants in arms; and in the last few weeks I have come across a discussion of 'Coitus in Childhood' by Dr. Stekel (1895) in Vienna. I have not had time to collect other published evidence; but even if it were only scanty, it is to be expected that increased attention to the subject will very soon confirm the great frequency of sexual experiences and sexual activity in childhood.

Lastly, the findings of my analysis are in a position to speak for themselves. In all eighteen cases (cases of pure hysteria and of hysteria combined with obsessions, and comprising six men and twelve women) I have, as I have said, come to learn of sexual experiences of this kind in childhood. I can divide my cases into three groups, according to the origin of the sexual stimulation. In the first group it is a question of assaults - of single, or at any rate isolated, instances of abuse, mostly practised on female children, by adults who were strangers, and who, incidentally, knew how to avoid inflicting gross, mechanical injury. In these assaults there was no question of the child's consent, and the first effect of the experience was preponderantly one of fright. The second group consists of cases in which some adult looking after the child - a nursery maid or governess or tutor, or, unhappily all too often, a close relative - has initiated the child into sexual intercourse and has maintained a regular love relationship with it - a love relationship, moreover, with its mental side developed - which has often lasted for years. The third group, finally, contains child-relationships proper - sexual relations between two children of different sexes, mostly a brother and sister, which are often prolonged beyond puberty and which have the most far-reaching consequences for the pair. In most of my cases I found that two or more of these aetiologies were in operation together; in a few instances the accumulation of sexual experiences coming from different quarters was truly amazing. You will easily understand this peculiar feature of my observations, however, when you consider that the patients I was treating were all cases of severe neurotic illness which threatened to make life impossible.

Where there had been a relation between two children I was sometimes able to prove that the boy - who, here too, played the part of the aggressor - had previously been seduced by an adult of the female sex, and that afterwards, under the pressure of his prematurely awakened libido and compelled by his memory, he tried to repeat with the little girl exactly the same practices that he had learned from the adult woman, without making any modification of his own in the character of the sexual activity.

In view of this, I am inclined to suppose that children cannot find their way to acts of sexual aggression unless they have been seduced previously. The foundation for a neurosis would accordingly always be laid in childhood by adults, the children themselves would transfer to one another the disposition to fall ill of hysteria later. I will ask you to consider a moment longer the special frequency with which sexual relations in childhood occur precisely between brothers and sisters and cousins, as a result of their opportunities for being together so often; supposing, then, ten or fifteen years later several members of the younger generation of the family are found to be ill, might not this appearance of a family neurosis naturally lead to the false supposition that a hereditary disposition is present where there is only a *pseudo-heredity* and where in fact what has taken place is a handing-on, an infection in childhood?

Now let us turn to the other objection, which is based precisely on an acknowledgement of the frequency of infantile sexual experiences and on the observed fact that many people who remember scenes of that kind have *not* become hysterics. Our first reply is that the excessive frequency of an aetiological factor cannot possibly be used as an objection to its aetiological significance. Is not the tubercle bacillus ubiquitous and is it not inhaled by far more people than are found to fall ill of tuberculosis? And is its aetiological significance impaired by the fact that other factors must obviously be at work too before the tuberculosis, which is its specific effect, can be evoked? In order to establish the bacillus as the specific aetiology it is enough to show that tuberculosis cannot possibly occur without its playing a part. The same doubtless applies to our problem. It does not matter if many people experience infantile sexual scenes without becoming hysterics, provided only that all the people who become hysterics have experienced scenes of that kind. The area of occurrence of an aetiological factor may be freely allowed to be wider than that of its effect, but it must not be narrower. Not everyone who touches or comes near a smallpox patient develops smallpox; nevertheless infection from a smallpox patient is almost the only known aetiology of the disease.

It is true that if infantile sexual activity were an almost universal occurrence the demonstration of its presence in every case would carry no weight. But, to begin with, to assert such a thing would certainly be a gross exaggeration; and secondly, the aetiological pretensions of the infantile scenes rest not only on the regularity of their appearance in the anamneses of hysterics, but, above all, on the evidence of there being associative and logical ties between those scenes and the hysterical symptoms - evidence which, if you were given the complete history of a case, would be as clear as daylight to you.

What can the other factors be which the 'specific aetiology' of hysteria still needs in order actually to produce the neurosis? That, Gentlemen, is a theme in itself, which I do not propose to enter upon. To-day I need only indicate the point of contact at which the two parts of the topic - the specific and the auxiliary aetiology - fit into one another. No doubt a considerable quantity of factors will have to be taken into account. There will be the subject's inherited and personal constitution, the inherent importance of the infantile sexual experiences, and, above all, their number: a brief relationship with a strange boy, who afterwards becomes indifferent, will leave a less powerful effect on a girl than intimate sexual relations of several years' standing with her own brother. In the aetiology of the neuroses quantitative preconditions are as important as qualitative ones: there are threshold-values which have to be crossed before the illness can become manifest. Moreover, I do not myself regard this aetiological series as complete; nor does it solve the riddle of why hysteria is not more common among the lower classes. (You will remember, by the way, what a surprisingly large incidence of hysteria was reported by Charcot among working-class *men*). I may also remind you that a few years ago I myself pointed out a factor, hitherto little considered, to which I attribute the leading role in provoking hysteria after puberty. I then put forward the view that the outbreak of hysteria may almost invariably be traced to a *psychical conflict* arising through an incompatible idea setting in action a *defence* on the part of the ego and calling up a demand for repression. What the circumstances are in which a defensive endeavour of this kind has the pathological effect of actually thrusting the memory which is distressing to the ego into the unconscious and of creating a hysterical symptom in its place I was not able to say at that time. But to-day I can repair the omission. *The defence achieves its purpose of thrusting the incompatible idea out of consciousness if there are infantile sexual scenes present in the (hitherto normal) subject in the form of unconscious memories, and if the idea that is to be repressed can be brought into logical or associative connection with an infantile experience of that kind.*

Since the ego's efforts at defence depend upon the subject's total moral and intellectual development, the fact that hysteria is so much rarer in the lower classes than its specific aetiology would warrant is no longer entirely incomprehensible.

Let us return once again, Gentlemen, to the last group of objections, the answering of which has led us such a long way. We have heard and have acknowledged that there are numerous people who have a very clear recollection of infantile sexual experiences and who nevertheless do not suffer from hysteria. This objection has no weight; but it provides an occasion for making a valuable comment. According to our understanding of the neurosis, people of this kind *ought* not to be hysterical at all, or at any rate, not hysterical as a result of the scenes which they consciously remember. With our patients, those memories are never conscious; but we cure them of their hysteria by transforming their unconscious memories of the infantile scenes into conscious ones. There was nothing that we could have done or needed to do about the fact that they have had such experiences. From this you will perceive that the matter is not merely one of the existence of the sexual experiences, but that a psychological precondition enters in as well. The scenes must be present as *unconscious memories*; only so long as, and in so far as, they are unconscious are they able to create and maintain hysterical symptoms. But what decides whether those experiences produce conscious or unconscious memories - whether that is conditioned by the content of the experiences, or by the time at which they occur, or by later influences - that is a fresh problem, which we shall prudently avoid. Let me merely remind you that, as its first conclusion, analysis has arrived at the proposition that *hysterical symptoms are derivatives of memories which are operating unconsciously*.

(c) Our view then is that infantile sexual experiences are the fundamental precondition for hysteria, are, as it were, the *disposition* for it and that it is they which create the hysterical symptoms, but that they do not do so immediately, but remain without effect to begin with and only exercise a pathogenic action later, when they have been aroused after puberty in the form of unconscious memories. If we maintain this view, we shall have to come to terms with the numerous observations which show that a hysterical illness may already make its appearance in childhood and before puberty. This difficulty, however, is cleared up as soon as we examine more closely the data gathered from analyses concerning the chronology of the infantile experiences. We then learn that in our severe cases the formation of hysterical symptoms begins - not in exceptional instances, but, rather, as a regular thing - at the age of eight, and that the sexual experiences which show no immediate effect invariably date further back, into the third or fourth, or even the second year of life. Since in no single instance does the chain of effective experiences break off at the age of eight, I must assume that this time of life, the period of growth in which the second dentition takes place, forms a boundary line for hysteria, after which the illness cannot be caused. From then on, a person who has not had sexual experiences earlier can no longer become disposed to hysteria; and a person who *has* had experiences earlier, is already able to develop hysterical symptoms. Isolated instances of the occurrence of hysteria on the other side of this boundary line (that is, *before* the age of eight) may be interpreted as a phenomenon of precocious maturity. The existence of this boundary-line is very probably connected with developmental processes in the sexual system. Precocity of somatic sexual development may often be observed, and it is even possible that it can be promoted by too early sexual stimulation.

In this way we obtain an indication that a certain *infantile* state of the psychical functions, as well as of the sexual system, is required in order that a sexual experience occurring during this period shall later on, in the form of a memory, produce a pathogenic effect. I do not venture as yet, however, to make any more precise statement on the nature of this psychical infantilism or on its chronological limits.

(d) Another objection might arise from exception being taken to the supposition that the *memory* of infantile sexual experiences produces such an enormous pathogenic effect, while the actual experience itself has none. And it is true that we are not accustomed to the notion of powers emanating from a mnemonic image which were absent from the real impression. You will moreover notice the consistency with which the proposition that symptoms can only proceed from memories is carried through in hysteria. None of the later scenes, in which the symptoms arise, are the effective ones; and the experiences which *are* effective have at first no result. But here we are faced with a problem which we may very justifiably keep separate from our theme. It is true that we feel impelled to make a synthesis, when we survey the number of striking conditions that we have come to know: the fact that in order to form a hysterical symptom a defensive effort against a distressing idea must be present, that this idea must exhibit a logical or associative connection with an unconscious memory through a few or many intermediate links, which themselves, too, remain unconscious at the moment, that this unconscious memory must have a sexual content, that its content must be an experience which occurred during a certain infantile period of life. It is true that we cannot help asking ourselves how it comes about that this memory of an experience that was innocuous at the time it happened, should posthumously produce the abnormal effect of leading a psychical process like defence to a pathological result, while it itself remains unconscious.

But we shall have to tell ourselves that this is a purely psychological problem, whose solution may perhaps necessitate certain hypotheses about normal psychical processes and about the part played in them by consciousness, but that this problem may be allowed to remain unsolved for the time being, without detracting from the value of the insight we have so far gained into the aetiology of hysterical phenomena.

III

Gentlemen, the problem, the approaches to which I have just formulated, concerns the *mechanism* of the formation of hysterical symptoms. We find ourselves obliged, however, to describe the *causation* of those symptoms without taking that mechanism into account, and this involves an inevitable loss of completeness and clarity in our discussion. Let us go back to the part played by the infantile sexual scenes. I am afraid that I may have misled you into over-estimating their power to form symptoms. Let me, therefore, once more stress the fact that every case of hysteria exhibits symptoms which are determined, not by infantile but by later, often by recent, experiences. Other symptoms, it is true, go back to the very earliest experiences and belong, so to speak, to the most ancient nobility. Among these latter are above all to be found the numerous and diverse sensations and paraesthesias of the genital organs and other parts of the body, these sensations and paraesthesias being phenomena which simply correspond to the sensory content of the infantile scenes, reproduced in a hallucinatory fashion, often painfully intensified.

Another set of exceedingly common hysterical phenomena - painful need to urinate, the sensation accompanying defaecation, intestinal disturbances, choking and vomiting, indigestion and disgust at food - were also shown in my analyses (and with surprising regularity) to be derivatives of the same childhood experiences and were explained without difficulty by certain invariable peculiarities of those experiences. For the idea of these infantile sexual scenes is very repellent to the feelings of a sexually normal individual; they include all the abuses known to debauched and impotent persons, among whom the buccal cavity and the rectum are misused for sexual purposes. For physicians, astonishment at this soon gives way to a complete understanding. People who have no hesitation in satisfying their sexual desires upon children cannot be expected to jibe a finer shades in the methods of obtaining that satisfaction; and the sexual impotence which is inherent in children inevitably forces them into the same substitutive actions as those to which adults descend if they become impotent. All the singular conditions under which the ill-matched pair conduct their love-relations - on the one hand the adult, who cannot escape his share in the mutual dependence necessarily entailed by a sexual relationship, and who is yet armed with complete authority and the right to punish, and can exchange the one role for the other to the uninhibited satisfaction of his moods, and on the other hand the child, who in his helplessness is at the mercy of this arbitrary will, who is prematurely aroused to every kind of sensibility and exposed to every sort of disappointment, and whose performance of the sexual activities assigned to him is often interrupted by his imperfect control of his natural needs - all these grotesque and yet tragic incongruities reveal themselves as stamped upon the later development of the individual and of his neurosis, in countless permanent effects which deserve to be traced in the greatest detail. Where the relation is between two children, the character of the sexual scenes is none the less of the same repulsive sort, since every such relationship between children postulates a previous seduction of one of them by an adult. The psychical consequences of these child-relations are quite extraordinarily far-reaching; the two individuals remain linked by an invisible bond throughout the whole of their lives.

Sometimes it is the accidental circumstances of these infantile sexual scenes which in later years acquire a determining power over the symptoms of the neurosis. Thus, in one of my cases the circumstance that the child was required to stimulate the genitals of a grown-up woman with his foot was enough to fixate his neurotic attention for years on to his legs and to their function, and finally to produce a hysterical paraplegia. In another case, a woman patient suffering from anxiety attacks which tended to come on at certain hours of the day could not be calmed unless a particular one of her many sisters stayed by her side all the time. Why this was so would have remained a riddle if analysis had not shown that the man who had committed the assaults on her used to enquire at every visit whether this sister, who he was afraid might interrupt him, was at home.

It may happen that the determining power of the infantile scenes is so much concealed that, in a superficial analysis, it is bound to be overlooked. In such instances we imagine that we have found the explanation of some particular symptom in the content of one of the later scenes - until, in the course of our work, we come upon the same content in one of the *infantile* scenes, so that in the end we are obliged to recognize that, after all, the later scene only owes its power of determining symptoms to its agreement with the earlier one. I do not wish because of this to represent the later scenes being unimportant; if it was my task to put before you the rules that govern the formation of hysterical symptoms, I should have to include as one of them that the idea which is selected for the production of a symptom is one which has been called up by a combination of several factors and which has been aroused from various directions simultaneously. I have elsewhere tried to express this in the formula: *hysterical symptoms are overdetermined*.

One thing more, Gentlemen. It is true that earlier I put the relation between recent and infantile aetiology aside as a separate theme. Nevertheless, I cannot leave the subject without overstepping this resolution at least with one remark. You will agree with me that there is *one* fact above all which leads us astray in the psychological understanding of hysterical phenomena, and which seems to warn us against measuring psychical acts in hysterics and in normal people with the same yardstick. That fact is the discrepancy between psychically exciting stimuli and psychical reactions which we come upon in hysterical subjects. We try to account for it by assuming the presence in them of a general abnormal sensitivity to stimuli, and we often endeavour to explain it on a physiological basis, as if in such patients certain organs of the brain which serve to transmit stimuli were in a peculiar chemical state (like the spinal centres of a frog, perhaps, which has been injected with strychnine) or as if these cerebral organs had withdrawn from the influence of higher inhibiting centres (as in animals being experimented on under vivisection). Occasionally one or other of these concepts may be perfectly valid as an explanation of hysterical phenomena; I do not dispute this. But the main part of the phenomenon - of the abnormal, exaggerated, hysterical reaction to psychical stimuli - admits of another explanation, an explanation which is supported by countless examples from the analyses of patients. And this is as follows: *The reaction of hysterics is only apparently exaggerated; it is bound to appear exaggerated to us because we only know a small part of the motives from which it arises.*

In reality, this reaction is proportionate to the exciting stimulus; thus it is normal and psychologically understandable. We see this at once when the analysis has added to the manifest motives, of which the patient is conscious, those other motives, which have been operative without his knowing about them, so that he could not tell us of them.

I could spend hours demonstrating the validity of this important assertion for the whole range of psychical activity in hysteria, but I must confine myself here to a few examples. You will remember the mental 'sensitiveness' which is so frequent among hysterical patients and which leads them to react to the least sign of being depreciated as though they had received a deadly insult. What would you think, now, if you were to observe this high degree of readiness to feel hurt on the slightest occasion, if you came across it between two normal people, a husband and wife, perhaps? You would certainly infer that the conjugal scene you had witnessed was not solely the result of this latest trifling occasion, but that inflammable material had been piling up for a long time and that the whole heap of it had been set alight by the final provocation.

I would ask you to carry this line of thought over on to hysterical patients. It is not the latest slight - which, in itself, is minimal - that produces the fit of crying, the outburst of despair or the attempt at suicide, in disregard of the axiom that an effect must be proportionate to its cause; the small slight of the present moment has aroused and set working the memories of very many, more intense, earlier slights, behind all of which there lies in addition the memory of a serious slight in childhood which has never been overcome. Or again, let us take the instance of a young girl who blames herself most frightfully for having allowed a boy to stroke her hand in secret, and who from that time on has been overtaken by a neurosis. You can, of course, answer the puzzle by pronouncing her an abnormal, eccentrically disposed and over-sensitive person; but you will think differently when analysis shows you that the touching of her hand reminded her of another, similar touching, which had happened very early in her childhood and which formed part of a less innocent whole, so that her self-reproaches were actually reproaches about that old occasion. Finally, the problem of the hysterogenic points is of the same kind. If you touch a particular spot, you do something you did not intend: you awaken a memory which may start off a convulsive attack, and since you know nothing of this psychical intermediate link you refer the attack directly to the operation of your touch. The patients are in the same state of ignorance and therefore fall into similar errors. ie they too are unaware of the re-awakening of the unconscious memory. They constantly establish 'false connections' between the most recent cause, which they are conscious of, and the effect, which depends on so many intermediate links. If, however, the physician has been able to bring together the conscious and unconscious motives for the purpose of explaining a hysterical reaction, he is almost always obliged to recognize that the seemingly exaggerated reaction is appropriate and is abnormal only in its form.

You may, however, rightly object to this justification of the hysterical reaction to psychical stimuli and say that nevertheless the reaction is not a normal one. For why do healthy people behave differently? Why do not all *their* excitations of long ago come into operation once more when a new, present-day, excitation takes place? One has an impression, indeed, that with hysterical patients it is as if all their old experiences - to which they have already reacted so often and, moreover, so violently - had retained their effective power; as if such people were incapable of disposing of their psychical stimuli. Quite true, Gentlemen, something of the sort must really be assumed. You must not forget that in hysterical people when there is a present-day precipitating cause, the old experiences come into operation in the form of *unconscious memories*. It looks as though the difficulty of disposing of a present impression, the impossibility of transforming it into a powerless memory, is attached precisely to the character of the psychical unconscious. You see that the remainder of the problem lies once more in the field of psychology - and, what is more, a psychology of a kind for which philosophers have done little to prepare the way for us.

To this psychology, which has yet to be created to meet our needs - to this future *psychology of the neuroses* - I must also refer you when, in conclusion, I tell you something which will at first make you afraid that it may disturb our dawning comprehension of the aetiology of hysteria. For I must affirm that the aetiological role of infantile sexual experience is not confined to hysteria but holds good equally for the remarkable neurosis of obsessions, and perhaps also, indeed, for the various forms of chronic paranoia and other functional psychoses. I express myself on this with less definiteness, because I have as yet analysed far fewer cases of obsessional neurosis than of hysteria; and as regards paranoia, I have at my disposal only a single full analysis and a few fragmentary ones. But what I discovered in these cases seemed to be reliable and filled me with confident expectations for other cases. You will perhaps remember that already, at an earlier date, I recommended that hysteria and obsessions should be grouped together under the name of '*neuroses of defence*', even before I had come to know of their common infantile aetiology. I must now add that although this need not be expected to happen in general - every one of my cases of obsessions revealed a substratum of hysterical symptoms, mostly sensations and pains, which went back precisely to the earliest childhood experiences. What, then, determines whether the infantile sexual scenes which have remained unconscious will later on, when the other pathogenic factors are super-added, give rise to hysterical or to obsessional neurosis or even to paranoia? This increase in our knowledge seems, as you see, to prejudice the aetiological value of these scenes, since it removes the specificity of the aetiological relation.

I am not yet in a position, Gentlemen, to give a reliable answer to this question. The number of cases I have analysed is not large enough nor have the determining factors in them been sufficiently various. So far, I have observed that obsessions can be regularly shown by analysis to be disguised and transformed *self-reproaches about acts of sexual aggression in childhood*, and are therefore more often met with in men than in women, and that men develop obsessions more often than hysteria. From this I might conclude that the character of the infantile scenes - whether they were experienced with pleasure or only passively - has a determining influence on the choice of the later neurosis; but I do not want to underestimate the significance of the age at which these childhood actions occur, and other factors as well. Only a discussion of further analyses can throw light on these points. But when it becomes clear which are the decisive factors in the choice between the possible forms of the neuro-psychoses of defence, the question of what the mechanism is in virtue of which that particular form takes shape will once again be a purely psychological problem.

I have now come to the end of what I have to say to-day. Prepared as I am to meet with contradiction and disbelief, I should like to say one thing more in support of my position. Whatever you may think about the conclusions I have come to, I must ask you not to regard them as the fruit of idle speculation. They are based on a laborious individual examination of patients which has in most cases taken up a hundred or more hours of work. What is even more important to me than the value you put on my results is the attention you give to the procedure I have employed. This procedure is new and difficult to handle, but it is nevertheless irreplaceable for scientific and therapeutic purposes. You will realize, I am sure, that one cannot properly deny the findings which follow from this modification of Breuer's procedure so long as one puts it aside and uses only the customary method of questioning patients. To do so would be like trying to refute the findings of histological technique by relying upon macroscopic examination. The new method of research gives wide access to a new element in the psychical field of events, namely, to processes of thought which have remained unconscious - which, to use Breuer's expression, are 'inadmissible to consciousness'. Thus it inspires us with the hope of a new and better understanding of all functional psychical disturbances. I cannot believe that psychiatry will long hold back from making use of this new pathway to knowledge.

ABSTRACTS OF THE SCIENTIFIC WRITINGS OF DR. SIGM. FREUD 1877-1897
(1897)

Intentionally left blank

ABSTRACTS OF THE SCIENTIFIC WRITINGS OF DR. SIGM. FREUD
1877-1897

A

BEFORE APPOINTMENT AS PRIVATDOZENT

I

'Observations on the configuration and finer structure of the lobed organs in eels described as testes.'

Dr. Syrski had recently recognized a paired, lobulated, grooved organ occurring in the abdominal cavity of the eel as the animal's male sexual organ which had long been looked for. At Professor Claus's suggestion I investigated the occurrence and tissue components of these lobed organs at the zoological station in Trieste.

II

'On the origin of the posterior nerve-roots in the spinal cord of *Ammocoetes* (*Petromyzon planeri*).'
(From the Institute of Physiology of the University of Vienna. With one plate.)

Investigation of the spinal cord of *Ammocoetes* showed that the large nerve-cells described by Reissner as occurring in the posterior grey matter (posterior cells) give rise to the root fibres of the posterior roots.- The anterior and posterior spinal roots of the *Petromyzon*, at all events in the caudal region, are displaced relatively to each other in their origins and remain distinct from each other in their peripheral course.

III

‘On the spinal ganglia and spinal cord of *Petromyzon*.’

(From the Institute of Physiology of the University of Vienna. With four plates and two woodcuts.)

The spinal ganglion cells of fish were long regarded as *bipolar*, and those of the higher animals were considered to be *unipolar*. As regards the latter elements Ranvier had shown that their single process branched in a T-shape after a short course. - By the use of a gold maceration technique it was possible to make a complete survey of the spinal ganglia of *Petromyzon*; their nerve cells exhibit every transition between bipolarity and unipolarity with T-shaped branching of the fibres; the number of fibres of the posterior root is regularly greater than the number of nerve cells in the ganglion; thus there are ‘fibres of passage’ and ‘subsidiary’ nerve fibres, of which the latter merely mingle with the elements of the roots. - A link between the spinal ganglion cells and the posterior cells in the spinal cord which have been described is provided in *Petromyzon* by cellular elements which are exposed on the surface of the spinal cord between the posterior root and ganglion. These scattered cells indicate the path taken by the spinal ganglion cells in the course of evolution. - In relation to the spinal cord of *Petromyzon*, the paper further describes the branching of the fibres in the central pathway of the posterior root fibres, and the forked ramification of the anterior commissural fibres, the intercalation of nerve cells in the spinal portions of the anterior roots, and a very fine nerve-net (which can be stained by gold chloride) in the pia mater.

IV

‘Note upon a method for anatomical preparations of the nervous system.’

A modification of a method recommended by Reichert. - A mixture of 1 part concentrated nitric acid, 3 parts water, and 1 part concentrated glycerine, since it destroys connective tissue and makes it easy to remove bones and muscles, is useful for laying bare the central nervous system with its peripheral branches, particularly in small mammals.

V

‘On the structure of the nerve fibres and nerve cells of the river crayfish.’

The nerve fibres of the river crayfish, when the tissues are examined live, exhibit without exception a fibrillary structure. The nerve cells, whose survival can be recognized from the granules in their nucleus, seem to be composed of two substances. One of these is reticular and is continued into the fibrils of the nerve fibres, and the other is homogeneous and is continued in their ground substance.

VI

‘The structure of the elements of the nervous system.’

(Lecture delivered before the Psychiatric Society, 1882.)

Contents as in V.

VII

‘A new method for the study of nerve-tracts in the central nervous system.’

If fine sections of the central organ, hardened in chromate are treated with gold chloride, a strong solution of soda and a 10 percent solution of calcium iodide, a red to blue stain is obtained which affects either the medullary sheaths or only the axis cylinders. The method is no more reliable than other methods of gold staining.

VIIa

‘A new histological method for the study of nerve-tracts in the brain and spinal chord.’

Contents as in VII.

VIII

‘A case of cerebral haemorrhage with indirect basal focal symptoms in a patient suffering from scurvy.’

A report of a case of cerebral haemorrhage in a patient suffering from scurvy, which ran a rapid course under continuous observation. The symptoms are explained with reference to Wernicke’s theory of the indirect effect of focal lesions.

IX

‘On Coca.’

The alkaloid of the coca plant which was described by Niemann received little attention for medical purposes at the time. My work included botanical and historical notes on the coca plant based on statements in the literature; it confirmed by experiments on normal subjects the remarkable stimulating effects of cocaine and its action in preventing hunger, thirst and sleep; and it endeavoured to lay down indications for the therapeutic use of the drug.

Among these indications the reference to the possible employment of cocaine during withdrawal of morphine became of importance later. The expectation voiced at the end of the work that the property of cocaine for producing local anaesthesia would find further applications was soon afterwards fulfilled by K. Koller’s experiments in anaesthetizing the cornea.

X

‘Contribution to our knowledge of the effects of coca.’

Dynamometric demonstration of the increase in motor strength during cocaine euphoria, motor strength (measured by the strength of the grip) shows a regular daily oscillation (similar to that of body temperature).

XI

‘A note upon the inter-olivary tract.’

Short notes on the connections of the roots of the auditory nerve and the connection between the inter-olivary tract and the crossed trapezoid body, based upon incompletely myelinated human preparations.

XII

‘A case of muscular atrophy with extensive disturbances of sensibility (syringomyelia).’

The combination of bilateral muscular atrophy, of bilateral disturbance of sensibility in the nature of a ‘partial’, dissociated paralysis of sensation, and of trophic disturbances in the left hand (which also exhibited the most intense anaesthesia), taken together with the restriction of the pathological symptoms to the upper part of the body, permitted a diagnosis *in vivo* in a 36-year-old man of syringomyelia, an affection which at that time was regarded as rare and hard to recognize.

B

AFTER APPOINTMENT AS PRIVATDOZENT

XIII

‘Acute multiple neuritis of the spinal and cranial nerves.’

An eighteen-year-old man fell ill without fever but with general symptoms and dragging pains in his chest and legs. At first he showed symptoms of endocarditis, but later the pains increased and sensitiveness to pressure developed in the vertebral column and regionally in the skin, muscles and nerve trunks as the affection involved one extremity after the other: heightening of the reflexes, outbreaks of sweating, local wasting, and lastly diplopia, disturbances of swallowing, facial paresis, and hoarseness. Finally fever, extreme acceleration of the pulse and pulmonary affection. The diagnosis of acute multiple neuritis made during the course of the illness was confirmed by the post-mortem findings, which showed that all the spinal nerves in their sheaths were injected, greyish-red, and, as it were, bunched up. Similar changes in the cranial nerves. Endocarditis. - According to the pathologist, this was the first post-mortem finding of polyneuritis to be made in Vienna.

XIV

‘On the relation of the restiform body to the posterior column and its nucleus with some remarks on two fields of the medulla oblongata.’

Jointly with Dr. L. Darkschewitsch (Moscow).

By studying preparations with incompletely myelinated medulla the restiform body can be divided into two components: a ‘nucleus’ (primary restiform body) and a ‘fringe’ (secondary restiform body). The latter contains the olivary fibre system which becomes medullated later. The primary restiform body, which is medullated earlier, is divided into a ‘head portion’ and a ‘tail portion’. The head of the primary restiform body arises from the nucleus of the column of Burdach and thus represents a (for the most part uncrossed) continuation to the cerebellum of the centripetal tract from the extremities. The corresponding continuation to the cerebrum is provided by means of the arcuate fibres originating from this same nucleus. The tail portion of the primary restiform body is a direct continuation of the spinal lateral cerebellar tract. - The lateral field of the medulla oblongata allows of a uniform interpretation of its components. It contains four grey substances with the systems of fibres proceeding from them, which are to be considered homologous to one another as substances in which the sensory nerves from the extremities, and the trigeminal, vagal, and auditory nerves have their origin.

XV

‘On the origin of the auditory nerve.’

A description of the origin of the auditory nerve, based on preparations of the human foetus, illustrated by four drawings of cross-sections and a diagram. The auditory nerve falls into three portions, of which the lowest (most spinal) terminates in the auditory ganglion and has continuations through the cornu trapezoides and the tracts of the superior olivary body; the second can be traced as the ‘ascending’ auditory root of Roller into what is known as Deiters’ nucleus; and the third runs into the inner auditory field of the medulla oblongata, from which continuations into the cerebellum arise. Details are given of the further course of these tracts so far as it has been possible to follow them.

XVI

‘Observation of a severe case of hemi-anaesthesia in a hysterical male.’
(The organ of vision was examined by Dr. Königstein.)

The case history of a 29-year-old engraver with a bad family history, who fell ill after a dispute with his brother. The case afforded a demonstration of the symptom of sensible and sensorial hemi-anaesthesia in its classical form. - The disturbance in the field of vision and in the sense of colour is reported by Dr. Königstein.

XVII

‘Remarks on addiction to cocaine and the fear of cocaine.’
(With reference to a lecture by W. A. Hammond.)

The employment of cocaine for the relief of abstinence from morphine resulted in the misuse of cocaine and gave physicians an opportunity of observing the new clinical picture of chronic cocaine addiction. My essay, supported by a pronouncement from an American neuropathologist, seeks to show that this addiction to cocaine comes about only in addicts to other drugs (such as morphine) and that cocaine itself cannot be blamed for it.

XVIII

‘On hemianopsia in earliest childhood.’

An observation of disturbance in one half of the visual field in two children, aged 26 months and three and a quarter years, an age at which the symptom had not previously been medically recorded. A discussion on the lateral inclination of the head and eyes which was to be observed in one of the cases and on the localization of the suspected lesion. Both cases are to be classed among the ‘unilateral cerebral palsies of children’.

XIX

On the Interpretation of the Aphasias, a critical study.

After a firm basis for the understanding of cerebral disturbances of speech had been established by the discovery and definite localization of a motor and a sensory aphasia (Broca and Wernicke), the authorities set about tracing the more subtle symptoms of aphasia as well to factors of localization. In this way they arrived at the hypothesis of a *conduction* aphasia, with subcortical and transcortical, and motor and sensory forms. This critical study is directed against this view of speech disorders and it seeks to introduce for their explanation functional factors in place of the topographical ones. The forms described as subcortical and transcortical are not to be explained by a particular localization of the lesion but by conditions of reduced capacity for conduction in the apparatus of speech. In fact there are no aphasias caused by subcortical lesion. The justification for distinguishing a central aphasia from a conduction aphasia is also disputed. The speech area of the cortex is seen rather as a continuous region of the cortex inserted between the motor fields of the cortex and those of the optic and auditory nerves—a region within which all communication and association subserving speech function takes place. The so-called speech-centres revealed by the pathology of the brain correspond merely to the corners of this field of speech; they are not distinguished functionally from the interior regions; it is only on account of their position in relation to the contiguous cortical centres that they produce more obvious signs when they become disordered.

The nature of the subject treated here called at many points for a closer investigation of the delimitation between the physiological and the psychological approach. Meynert's and Wernicke's views on the localization of ideas in nervous elements have had to be rejected and Meynert's account of a representation of the body in the cerebral cortex has required revision. Two facts of cerebral anatomy, namely (1) that the masses of fibres entering the spinal cord are constantly diminished on passing upwards, owing to the interposition of grey matter, and (2) that there are no direct paths from the periphery of the body to the cortex - these two facts lead to the conclusion that a really complete representation of the body is present only in the grey matter of the cord (as a 'projection'), whereas in the cortex the periphery of the body is only 'represented' in less detail through selected fibres arranged according to function.

XX

Clinical Studies of the Unilateral Cerebral Palsies of Children.

(In collaboration with Dr. O. Rie.)

(No. III of *Beiträge zur Kinderheilkunde* edited by Dr. M. Kassowitz.)

A monograph describing this affection, based on studies of material in the First Public Institute for Children's Diseases in Vienna, directed by Kassowitz. In ten sections it deals with (1) the history and literature of the cerebral palsies of children; (2) 35 observations of the authors' own, which are then summarized in tabular form and described individually; (3) the analysis of the individual symptoms of the clinical picture; (4) the pathological anatomy; (5) the relations of cerebral palsy to epilepsy and, (6) to infantile poliomyelitis; (7) differential diagnosis and (8) therapy. A 'choreatic paresis' is described by the authors for the first time; it is distinguished by peculiar characteristics in its onset and course, and in it the unilateral paresis is from the beginning represented by hemichorea. There is further an account of the findings of an autopsy (lobar sclerosis as a result of an embolism of the middle cerebral artery) on a woman patient described in the *Iconographie de la Saltpêtrière*. Emphasis is laid on the close relations between epilepsy and the cerebral palsies of children, in consequence of which some cases of apparent epilepsy might deserve to be described as 'cerebral palsy without palsy'. In connection with the much discussed question as to the existence of a *polioencephalitis acuta*, which is supposed to constitute the anatomical basis of unilateral cerebral palsy and to offer a complete analogy with *poliomyelitis infantilis*, the authors argue against this hypothesis of Strümpell's; but they hold firmly to the expectation that a modified view of *poliomyelitis acuta infantilis* will allow of its being equated with cerebral palsy on another basis. In the therapeutic section are collected the hitherto published reports on the intervention by brain surgeons directed to the cure of genuine or traumatic epilepsy.

XXI

'A case of successful treatment by hypnotism with some remarks on the origin of hysterical symptoms through "counter will".'

A young woman after the birth of her first child was compelled to give up breast-feeding it owing to a complex of hysterical symptoms (loss of appetite, sleeplessness, pains in her breasts, failure of milk-secretion, agitation). When, after the birth of a second child, these obstacles recurred, deep hypnosis on two occasions, accompanied by counter-suggestions, succeeded in removing the obstacles, so that the patient became an excellent nursing mother. The same result was brought about a year later in similar circumstances after two more hypnoses. Some remarks are appended on the fact that it is possible in hysterical patients for distressing antithetic or anxious ideas to be realized which normal people are able to inhibit; several observations of *tic* are traced back to this mechanism of 'counter-will'.

XXII

'Charcot.'

An obituary of the master of neuropathology who died in 1893 and among whose pupils the present writer numbers himself.

XXIII

'On a symptom which often accompanies *enuresis nocturna* in children.'

In perhaps half the cases of children suffering from enuresis we find a hypertonia of the lower extremities the significance and implications of which are unexplained.

XXIV

'On the psychical mechanism of hysterical phenomena.'
(Preliminary communication in collaboration with Dr. J. Breuer.)

The mechanism to which Charcot traced back hystero-traumatic paralyses, and the assumption of which enabled him to provoke them deliberately in hypnotized hysterical patients, can also be made responsible for numerous symptoms of what is described as non-traumatic hysteria. If we put the hysteric under hypnosis and lead his thoughts back to the time at which the symptom in question first appeared, a memory of a psychical trauma (or series of traumas) belonging to that time awakens in him with hallucinatory vividness, the symptom having persisted as a mnemonic symbol of the trauma. Thus hysterics suffer mainly from reminiscences. If the traumatic scene which has been arrived at in this way is reproduced vividly, accompanied by a generation of affect, the symptom which has hitherto been obstinately maintained disappears. We must therefore suppose that the forgotten memory has been acting like a foreign body in the mind, with the removal of which the irritating phenomena cease. This discovery, first made by Breuer in 1881, can be made the basis of a therapy of hysterical phenomena which deserves to be described as 'cathartic'.

The memories which are revealed as 'pathogenic', as the roots of hysterical symptoms, are regularly 'unconscious' to the patient. It seems that by thus remaining unconscious they escape the wearing-away process to which psychical material is normally subject. A wearing-away of this sort is brought about by the method of 'abreaction'. Pathogenic memories avoid being dealt with by abreaction either because the experiences concerned have occurred in special psychical states to which hysterical persons are inherently inclined, or because those experiences have been accompanied by an affect which brings about a special psychical state in hysterical persons. A tendency to a 'splitting of consciousness' is accordingly the basic psychical phenomenon in cases of hysteria.

XXV

An Account of the Cerebral Diplegias of Childhood (in Connection with Little's Disease.)
(No. III, New Series, of *Beiträge zur Kinderheilkunde* edited by Dr. M. Kassowitz.)

A supplement to the *Clinical Study of the Unilateral Cerebral Palsies of Children* summarized under XX above. The history, pathological anatomy and physiology of the affection are treated here in the same order as in the earlier monograph, and the relevant clinical pictures are illustrated by 53 observations made by the author himself. It was, however, necessary in addition to take into account the range of forms that must be described as 'cerebral diplegias' and to point out their clinical similarity. In face of the differences of opinion that prevail in the literature of these disorders, the author has adopted the standpoint of an earlier authority, Little, and has thus arrived at the erection of four principal types, which are described as general spasticity, paraplegic spasticity, general chorea and bilateral athetosis, and bilateral spastic hemiplegia (spastic diplegia).

General spasticity includes the forms which are usually referred to as 'Little's disease'. Paraplegic spasticity is the name given to what was earlier regarded as a spinal affection, *tabes spastica infantilis*. The spastic diplegias correspond most easily to a doubling of unilateral cerebral palsies, but are characterized by a superfluity of symptoms which finds its explanation in the bilateral nature of the cerebral affection. The justification for including general chorea and bilateral athetosis among these types is provided by numerous characteristics of the clinical picture and by the existence of many mixed and transitional forms which link all these types together.

A discussion follows of the relations of these clinical types to the aetiological factors which are here assumed to be operative and to the insufficient number of post-mortem findings that have been reported. The following conclusions are reached:

Cerebral diplegias can be divided according to their origin into (a) those congenitally determined, (b) those arising at the time of birth and (c) those acquired after birth. But it is extremely rarely that this distinction can be drawn from the clinical peculiarities of the case, and not always possible from the anamnesis. All the aetiological factors of the diplegias are enumerated: prenatal (trauma, illness, or shock affecting the mother, place of the child in the family); operative at the time of birth (the factors stressed by Little, namely premature birth, difficult labour, asphyxia); and after birth (infectious diseases, trauma or shock affecting the child). Convulsions cannot be regarded as causes but only as symptoms of the affection. The aetiological part played by inherited syphilis is recognized as important. There is no exclusive relation between any one of these aetiologies and any one type of cerebral diplegia, but preferential relations are often apparent. The view that cerebral diplegias are affections with a single aetiology is untenable.

The pathological findings in the diplegias are of many kinds, and in general the same as in the hemiplegias; for the most part they are in the nature of end stages, from which it is not invariably possible to infer back to the initial lesions. They do not as a rule allow of a decision as to the aetiological category to which a case is to be referred. Nor is it usually possible to deduce the clinical picture from the post-mortem findings; so that the assumption that there are intimate and exclusive relations between clinical types and anatomical changes must also be rejected.

The pathological physiology of cerebral diplegias has an essential connection with the two characteristics by which both general and paraplegic spasticity are distinguished from other manifestations of organic disease of the cerebrum. For in both these clinical forms contracture predominates over paralysis and the lower extremities are affected more severely than the upper ones. The discussion in this paper reaches the conclusion that the more intense affection of the lower extremities in general and paraplegic spasticity must be connected with the localization of the lesion (meningeal haemorrhage along the median fissure) and the preponderance of contracture with the superficiality of the lesion. The strabismus of diplegic children, which is particularly common in paraplegic spasticity and where premature birth is the aetiology, is traceable to the retinal haemorrhages in new-born children described by Königstein.

A special section directs attention to the numerous instances of the familial and hereditary occurrence of children's diseases which show a clinical affinity with cerebral diplegias.

XXVI

‘On familial forms of cerebral diplegias.’

An observation of two brothers, one six and a half and the other five years old, whose parents were blood relations, and who present a complicated clinical picture which has gradually developed, in the one case since birth and in the other since the second year. The symptoms of this familial disorder (lateral nystagmus, atrophy of the optic nerve, alternating convergent strabismus, monotonous and, as it were, scanning speech, intention tremor of the arms, spastic weakness of the legs, accompanied by high intelligence) give grounds for constructing a new affection which is to be regarded as a spastic counterpart to Friedreich’s disease. Emphasis is laid on the far-reaching similarity of these cases to those described as multiple sclerosis by Pelizaeus in 1885.

XXVII

‘The cerebral diplegias of children.’

A summary of the findings in the monograph abstracted above, No. XXV.

XXVIII

‘Some points for a comparative study of organic and hysterical motor paralyses.’

A comparison between organic and hysterical paralyses made under the influence of Charcot in order to arrive at a line of approach to the nature of hysteria. Organic paralysis is either periphero-spinal or cerebral. On the basis of discussions in my critical study on the aphasias, the former is described as *projection* paralysis and is paralysis *en détail*, and the latter is described as *representation* paralysis and is paralysis *en masse*. Hysteria imitates only the latter category of paralyses but has freedom to specialize which makes it resemble projection paralysis; it can dissociate the areas of paralysis which regularly occur in cerebral affections. Hysterical paralysis has a tendency to excessive development; it can be extremely in tense and yet strictly confined to a small area, while cortical paralysis regularly increases its extent with an increase in its intensity. Sensibility behaves in a directly contrary manner in the two kinds of paralysis.

The special characteristics of cortical paralysis are determined by the peculiarities of cerebral structure, and allow us to infer back to the anatomy of the brain. Hysterical paralysis on the contrary behaves as though there were no such thing as cerebral anatomy. Hysteria knows nothing of the anatomy of the brain. The alteration which underlies hysterical paralysis can have no resemblance to organic lesions but must be looked for in the conditions governing the accessibility of some particular circle of ideas.

XXIX

‘The neuro-psychoses of defence: an attempt at a psychological theory of acquired hysteria, of many phobias and obsessions and of certain hallucinatory psychoses.’

The first of a series of short papers which now follow and which are directed to the task of preparing a general exposition of the neuroses on a new basis which is now in hand.

The splitting of consciousness in hysteria is not a primary characteristic of this neurosis, based on degenerative weakness, as Janet insists. It is the consequence of a peculiar psychical process known as ‘defence’ which is shown by some short reports of analyses to be present not only in hysteria but in numerous other neuroses and psychoses. Defence comes into operation when an instance of incompatibility arises in ideational life between a particular idea and the ‘ego’. The process of may be figuratively represented as though the quota of excitation were torn away from the idea that is to be repressed and put to some other use. This can occur in a variety of ways: in hysteria the liberated sum of excitation is transformed into somatic innervation (*conversion hysteria*); in obsessional neurosis it remains in the psychical field and attaches itself to other ideas which are not incompatible in themselves and which are thus *substitutes* for the repressed idea. The source of the incompatible ideas which are subjected to defence is solely and exclusively sexual life. An analysis of a case of hallucinatory psychosis shows that this psychosis too represents a method of achieving defence.

XXX

‘Obsessions and phobias: their psychical mechanism and aetiology.’

Obsessions and phobias are to be distinguished from neurasthenia as independent neurotic affections. In both it is a question of the linkage between an idea and an affective state. In phobias the latter is always the same, namely anxiety; in true obsessions it can be of various kinds (self-reproach, sense of guilt, doubt, etc.). The affective state emerges as the essential element of the obsession, since it remains unaltered in the individual case, whereas the idea attached to it is changed. Psychological analysis shows that the affect of the obsession is justified in every instance, but that the idea attached to it represents a substitute for an idea derived from sexual life which is more appropriate to the affect and which has succumbed to repression. This state of affairs is illustrated by numerous short analyses of cases of *folie du doute*, washing mania, arithmomania, etc., in which the reinstatement of the repressed idea was successful and accompanied by useful therapeutic effects. The phobias in the strict sense are reserved for the paper on anxiety neurosis (No. XXXII).

XXXI

Studies on Hysteria.

(In collaboration with Dr. J. Breuer.)

This volume contains the carrying-through of the subject raised in the 'Preliminary Communication' (No. XXIV) dealing with the psychical mechanism of hysterical phenomena. Although it proceeds from the joint work of the two authors, it is divided into separate sections, of which four detailed case histories together with discussions and an attempt at a 'Psychotherapy of Hysteria' represent my share. The aetiological part played by the sexual factor is stressed with greater emphasis in this book than in the 'Preliminary Communication', and the concept of 'conversion' is used to throw light on the formation of hysterical symptoms. The essay on psychotherapy seeks to give some insight into the technique of the psycho-analytic procedure, which is alone able to lead to the investigation of the unconscious content of the mind, and the employment of which may also be expected to lead to important psychological discoveries.

XXXII

'On the grounds for detaching a particular syndrome from neurasthenia under the description "anxiety neurosis".'

The concurrence of a constant grouping of symptoms with a particular aetiological determinant makes it possible to pick out from the composite province of 'neurasthenia' a syndrome which deserves the name of 'anxiety neurosis', because all of its constituents arise from the symptoms of anxiety. These are either to be regarded as immediate manifestations of anxiety or as rudiments and equivalents of them (E. Hecker), and they are often in complete opposition to the symptoms which constitute neurasthenia proper. The aetiology of the two neuroses also points to an opposition of this kind. Whereas true neurasthenia arises from spontaneous emissions or is acquired through masturbation, the factors belonging to the aetiology of anxiety neurosis are such as correspond to a holding back of sexual excitation - such as abstinence when libido is present, unconsummated excitation and, above all, coitus interruptus. In actual life the neuroses here distinguished usually appear in combination, though pure cases can also be demonstrated. When a mixed neurosis of this kind is subjected to analysis, it is possible to indicate a mixture of several specific aetiologies.

An attempt to arrive at a theory of anxiety neurosis leads to a formula to the effect that its mechanism lies in *the deflection of somatic sexual excitation from the psychical field* and a consequent abnormal employment of that excitation. *Neurotic anxiety is transformed sexual libido.*

XXXIII

'A reply to criticisms of my paper on anxiety neurosis.'

A reply to objections made by Löwenfeld to the content of No. XXXII. The problem of the aetiology of the pathology of the neuroses is dealt with here, to justify the division into three categories of the aetiological factors that appear: (a) preconditions, (b) specific causes and (c) concurrent or auxiliary causes. What are called preconditions are the factors which, though they are indispensable for producing the effect, cannot by themselves produce it but need in addition the specific causes. The specific causes are distinguished from the preconditions by the fact that they figure in only a few aetiological formulas, while the preconditions play the same part in numerous affections. Auxiliary causes are such as neither need invariably be present nor are able by themselves to produce the effect in question. - In the case of neuroses it is possible that the precondition may be heredity; the specific cause lies in sexual factors; everything else that is brought up apart from these as forming the aetiology of the neuroses (overwork, emotion, physical illness) is an auxiliary cause and can never entirely take the place of the specific factor, though it can no doubt serve as a substitute for it in the matter of *quantity*. The form of a neurosis depends on the nature of the specific sexual cause; whether there shall be a neurotic illness *at all* is determined by factors operating quantitatively; heredity works like a multiplier inserted in an electric circuit.

XXXIV

'On Bernhardt's disturbance of sensibility in the thigh.'

A self-observation of this harmless affection, which is probably traceable to local neuritis; and a report of some other cases, including bilateral ones.

XXXV

‘Further remarks on the neuro-psychoses of defence.’

(1) *The specific aetiology of hysteria.* A continuation of psycho-analytic work with hysterical subjects has had the uniform result of showing that the suspected traumatic events (as mnemonic symbols of which hysterical symptoms persist) occur in the patients’ *earliest childhood* and are to be described as sexual abuses in the narrowest sense.

(2) *The nature and mechanism of obsessional neurosis.* Obsessional ideas are invariably transformed self-reproaches which have re-emerged from repression and which always relate to some sexual act that was performed with pleasure in childhood. The course taken by this return of the repressed is traced, as are the results of a primary and secondary work of defence.

(3) *Analysis of a case of chronic paranoia.* This analysis, which is reported in detail, indicates that the aetiology of paranoia is to be found in the same sexual experiences of early childhood in which the aetiology of hysteria and of obsessional neurosis has already been discovered. The symptoms of this case of paranoia are traced in detail to the activities of defence.

XXXVI

‘The aetiology of hysteria.’

More detailed reports of the infantile sexual experiences which have been shown to constitute the aetiology of the psychoneuroses. In their content these experiences must be described as ‘perversions’, and those responsible are as a rule to be looked for among the patient’s nearest relatives. A discussion of the difficulties which have to be surmounted in uncovering these repressed memories and of the objections that may be raised against the results thus arrived at. Hysterical symptoms are shown to be derivatives of memories operating unconsciously; they appear only in collaboration with such memories. The presence of infantile sexual experiences is an indispensable condition if the efforts of defence (which occur in normal people as well) are to result in producing pathogenic effects - that is to say, neuroses.

XXXVII

‘Heredity and the aetiology of the neuroses.’

The findings hitherto arrived at by psycho-analysis on the aetiology of the neuroses are here employed to criticize the current theories of the omnipotence of heredity in neuropathology. The part played by heredity has been overestimated in several directions. Firstly, by including among the inheritable neuropathic illnesses conditions such as headaches, neuralgias, etc., which are very probably attributable as a rule to organic affections of the cranial cavities (the nose). Secondly, by regarding every discoverable nervous ailment among relatives as evidence of hereditary taint and by thus from the first leaving no room for *acquired* neuropathic illnesses which can possess no similar evidential weight. Thirdly, the aetiological role of syphilis has been misunderstood and the nervous ailments deriving from it have been put down to the account of heredity. But in addition, a general objection is permissible against a form of heredity which is described as ‘dissimilar inheritance’ (or inheritance with a change in the form of the illness), and to which a far more important part is allotted than to ‘similar’ inheritance. But when the fact of hereditary taint in a family is demonstrated in its members being affected alternatively by every sort of nervous complaint - chorea, epilepsy, hysteria, apoplexy, etc. - without any more precise determinants, then either we need a knowledge of the laws according to which these complaints replace one another or else room is left for the individual aetiologies which determine precisely the choice of the neuropathic state which in fact results from them. If such particular aetiologies exist, they are the specific causes, so much sought after, of the various different clinical forms, and heredity is pushed back into the role of a requirement or precondition.

XXXVIII

Infantile Cerebral Palsies.

This is a summary of the two works on the same theme published in 1891 and 1893, together with the additions and alterations which have since become necessary. These affect the chapter on *poliomyelitis acuta*, which has meantime been recognized as a non-systematic disease, on encephalitis as an initial process of spastic hemiplegia, and on the interpretation of cases of paraplegic spasticity, the cerebral nature of which affection may recently have been placed in doubt. A special discussion is concerned with the attempts to split up the content of the cerebral diplegias into several clearly divided clinical entities, or at least to separate what is known as 'Little's disease' as a clinical individual from among the medley of forms of similar affections. The difficulties which meet such attempts are pointed out, and it is maintained as the only justifiable view that 'infantile cerebral palsy' shall be retained at present as a collective clinical concept for a whole number of similar affections with an exogenous aetiology. The rapid increase in observations of familial and hereditary nervous disorders of children, which resemble infantile cerebral palsies clinically at many points, has made it a pressing matter to collect these new forms and to attempt to draw a fundamental distinction between them and infantile cerebral palsies.

SEXUALITY IN THE AETIOLOGY OF THE NEUROSES
(1898)

Intentionally left blank

SEXUALITY IN THE AETIOLOGY OF THE NEUROSES

Exhaustive researches during the last few years have led me to recognize that the most immediate and, for practical purposes, the most significant causes of every case of neurotic illness are to be found in factors arising from sexual life. This theory is not entirely new. A certain amount of importance has been allowed to sexual factors in the aetiology of the neuroses from time immemorial and by every writer on the subject. In certain marginal regions of medicine a cure for 'sexual complaints' and for 'nervous weakness' has always been promised in the same breath. When once the validity of the theory ceases to be denied, therefore, it will not be hard to dispute its originality.

In a few short papers which have appeared during the last years in the *Neurologisches Zentralblatt*, the *Revue Neurologique* and the *Wiener klinische Rundschau*, I have tried to give an indication of the material and the points of view which offer scientific support for the theory of the 'sexual aetiology of the neuroses'. A full presentation is, however, still wanting, mainly because, in endeavouring to throw light on what is recognized as the actual state of affairs, we come upon ever fresh problems for the solution of which the necessary preliminary work has not been done. It does not seem to me at all premature, however, to attempt to direct the attention of medical practitioners to what I believe to be the facts so that they may convince themselves of the truth of my assertions and at the same time of the benefits they may derive in their practice from a knowledge of them.

I am aware that efforts will be made, by the use of arguments with an ethical colouring, to prevent the physician from pursuing the matter further. Anyone who wants to make certain whether or not his patients' neuroses are really connected with their sexual life cannot avoid asking them about their sexual life and insisting upon receiving a true account of it. But in this, it is asserted, lies the danger both for the individual and society. A doctor, I hear it being said, has no right to intrude upon his patients' sexual secrets and grossly injure their modesty (especially with women patients) by an interrogation of this sort. His clumsy hand can only ruin family happiness, offend the innocence of young people and encroach upon the authority of parents; and where adults are concerned he will come to share uncomfortable knowledge and destroy his own relations to his patients. It is therefore his ethical duty, the conclusion is, to keep away from the whole business of sex.

To this one may well reply that it is the expression of a prudery which is unworthy of a physician and which inadequately conceals its weakness behind bad arguments. If factors arising out of sexual life must really be acknowledged to be causes of illness, then, for that very reason, investigation and discussion of them automatically falls within the sphere of a physician's duty. The injury to modesty of which he is guilty in this is no different and no worse, one would imagine, than when he insists on examining a woman's genital organs in order to cure a local affection - a demand on which he is pledged to insist by his medical training itself. Even now one often hears elderly women who have spent their youth in the provinces tell of how at one time they were reduced to a state of exhaustion by excessive genital haemorrhages, because they could not make up their minds to allow a doctor to see their nakedness. The educative influence which has been exercised on the public by the medical world has, in the course of one generation, so altered things that an objection of this sort is an extremely rare occurrence among the young women of to-day. If it were to occur, it would be condemned as unreasonable prudery, as modesty in the wrong place. Are we living in Turkey, a husband would ask, where all that a sick woman may show to the physician is her arm through a hole in the wall?

It is not true that interrogation of his patients and knowledge about their sexual concerns give the physician a dangerous degree of power over them. It was possible in earlier times for the same objection to be made against the uses of anaesthetics, which deprive the patient of his consciousness and of the exercise of his will and leave it to the doctor to decide whether and when he shall regain them. And yet to-day anaesthetics have become indispensable to us because they are able, better than anything else, to assist the doctor in his medical work; and among his many other serious obligations, he has taken over the responsibility for their use.

A doctor can always do harm if he is unskilful or unscrupulous, and this is no more and no less true where it is a question of investigating his patients' sexual life than it is in other things. Naturally, if someone, after an honest self-examination, feels that he does not possess the tact, seriousness and discretion which are necessary for questioning neurotic patients, and if he is aware that revelations of a sexual character would provoke lascivious thrills in him rather than scientific interest, then he will be right to avoid the topic of the aetiology of the neuroses. All we ask, in addition, is that he should also refrain from treating nervous patients.

Nor is it true that patients put insuperable obstacles in the way of an investigation into their sexual life. After some slight hesitation, adults usually adjust themselves to the situation by saying: 'After all, I'm at the doctor's; I can say anything to him.' A great many women who find it difficult enough to go through life concealing their sexual feelings, are relieved to find that with the doctor no other consideration outweighs that of their recovery, and they are grateful to him that for once they are allowed to behave quite humanly about sexual things. A dim knowledge of the overwhelming importance of sexual factors in the production of neuroses (a knowledge which I am trying to capture afresh for science) seems never to have been lost in the consciousness of laymen. How often do we witness scenes like this : A married couple, one of whom is suffering from a neurosis, comes to us for consultation. After we have made a great many introductory remarks and apologies to the effect that no conventional barriers should exist between them and the doctor who wants to be of use in such cases, and so on, we tell them that we suspect that the cause of the illness lies in the unnatural and detrimental form of sexual intercourse which they must have chosen since the wife's last confinement. We tell them that doctors do not as a rule concern themselves with such matters, but that that is reprehensible of them, even though the patients do not want to be told about things like that, etc. Thereupon one of the couple nudges the other and says: 'You see! I told you all along it would make me ill.' And the other answers: 'Well, I know, I thought so too; but what is one to do?'

In certain other circumstances, such as when one is dealing with young girls, who, after all, are systematically brought up to conceal their sexual life, one will have to be content with a very small measure of sincere response on the part of the patient. But an important consideration comes into play here namely that a doctor who is experienced in these things does not meet his patients unprepared and as a rule does not have to ask them for information but only for a confirmation of his surmises. Anyone who will follow my indications as to how to elucidate the morphology of the neuroses and translate it into aetiological terms, will need the addition of very few further admissions from his patients; in the very description of their symptoms, which they are only too ready to give, they have usually acquainted him at the same time with the sexual factors that are hidden behind.

It would be a great advantage if sick people had a better knowledge of the certainty with which a doctor is now in a position to interpret their neurotic complaints and to infer from them their operative sexual aetiology. It would undoubtedly spur such people on to abandon their secretiveness from the moment they have made up their minds to seek help for their sufferings. Moreover, it is in the interest of all of us that a higher degree of honesty about sexual things should become a duty among men and women than has hitherto been expected of them. This cannot be anything but a gain for sexual morality. In matters of sexuality we are at present, every one of us, ill or well, nothing but hypocrites. It will be all to our good if, as a result of such general honesty, a certain amount of toleration in sexual concerns should be attained.

Doctors usually take very little interest in a good many of the questions which are discussed among neuropathologists in connection with the neuroses: whether, for instance, one is justified in making a strict differentiation between hysteria and neurasthenia, whether one may distinguish hystero-neurasthenia alongside of them, whether obsessions should be classed with neurasthenia or recognized as a separate neurosis, and so on. And, indeed, such distinctions may well be a matter of indifference to a practitioner, so long as no further consequences follow from the decisions arrived at - no deeper insight and no pointers for therapeutic treatment - and so long as the patient will in every instance be sent off to a hydropathic establishment, and be told that there is nothing the matter with him. But it will be a different thing if our point of view about the causative relations between sexuality and the neuroses is adopted. Fresh interest is then aroused in the symptomatology of the different neurotic cases, and it becomes of practical importance that one should be able correctly to break down the complicated picture into its components and correctly to name them. For the morphology of the neuroses can with little difficulty be translated into aetiology and a knowledge of the latter leads on quite naturally to new indications for methods of cure.

Now the important decision we have to make - and this can be done with certainty in every instance if the symptoms are carefully assessed - is whether the case bears the characteristics of neurasthenia or of a psychoneurosis (hysteria, obsessions). (Mixed cases in which signs of neurasthenia are combined with signs of a psychoneurosis are of very frequent occurrence; but we will leave consideration of them till later.) It is only in neurasthenias that questioning the patient succeeds in disclosing the aetiological factors in his sexual life. These factors are, of course, known to him and belong to the present time, or, more properly, to the period of his life since sexual maturity (though this delimitation does not cover every case). In psychoneuroses questioning of this kind has little result. It may perhaps give us a knowledge of the factors which have to be recognized as precipitating ones, and these may or may not be connected with sexual life. If they are, they show themselves to be no different in kind from the aetiological factors of neurasthenia; that is, they entirely lack any specific relation to the causation of the psychoneurosis. And yet, in every instance, the aetiology of the psychoneuroses, too, lies in the field of sexuality. By a curious circuitous path, of which I shall speak later, it is possible to arrive at a knowledge of this aetiology and to understand why the patient was unable to tell us anything about it. For the events and influences which lie at the root of every psychoneurosis, belong, not to the present day, but to an epoch of life which is long past and which is, as it were, a prehistoric one - to the time of early childhood; and that is why the patient, too, knows nothing of them. He has - though only in a particular sense - forgotten them.

Thus, in every case of neurosis there is a sexual aetiology; but in neurasthenia it is an aetiology of a present-day kind, whereas in the psychoneuroses the factors are of an infantile nature. This is the first great contrast in the aetiology of the neuroses. 1 A second one emerges when we take account of a difference in the symptomatology of neurasthenia itself. Here, on the one hand, we find cases in which certain complaints characteristic of neurasthenia (intracranial pressure, proneness to fatigue, dyspepsia, constipation, spinal irritation, etc.) are prominent; in other cases these signs play a minor part and the clinical picture is composed of other symptoms, all of which exhibit a relation to the nuclear symptom, that of anxiety (free anxiousness, unrest, expectant anxiety, complete, rudimentary or supplementary anxiety attacks, locomotor vertigo, agoraphobia, insomnia, increased sensitivity to pain, and so on). I have left the name of neurasthenia to the first type, but have distinguished the second type as 'anxiety neurosis'; and I have given reasons for this separation in another place, where I have also taken account of the fact that as a rule both neuroses appear together. For the present purpose it is enough to emphasize that parallel to the difference in the symptoms of these two forms of illness there goes a difference in their aetiology. Neurasthenia can always be traced back to a condition of the nervous system such as is acquired by excessive masturbation or arises spontaneously from frequent emissions; anxiety neurosis regularly discloses sexual influences which have in common the factor of reservation or of incomplete satisfaction - such as coitus interruptus, abstinence together with a lively libido, so-called unconsummated excitation, and so on. In my short paper intended to introduce anxiety neurosis I put forward the formula that anxiety is always libido which has been deflected from its employment.

Where there is a case in which symptoms of neurasthenia and of anxiety neurosis are combined - where, that is, we have a mixed case - we have only to keep to our proposition, empirically arrived at, that a mingling of neuroses implies the collaboration of several aetiological factors, and we shall find our expectation confirmed in every instance. How often these aetiological factors are linked with one another organically, through the interplay of sexual processes - for instance, coitus interruptus or insufficient potency in the man, going along with masturbation - would well deserve separate discussion.

Having diagnosed a case of neurasthenic neurosis with certainty and having classified its symptoms correctly, we are in a position to translate the symptomatology into aetiology; and we may then boldly demand confirmation of our suspicions from the patient. We must not be led astray by initial denials. If we keep firmly to what we have inferred, we shall in the end conquer every resistance by emphasizing the unshakeable nature of our convictions. In this way we learn all sorts of things about the sexual life of men and women, which might well fill a useful and instructive volume; and we learn, too, to regret from every point of view that sexual science is even to-day still regarded as disreputable. Since minor deviations from a normal *vita sexualis* are much too common for us to attach any value to their discovery, we shall only allow a serious and long continued abnormality in the sexual life of a neurotic patient to carry weight as an explanation. Moreover, the idea that one might, by one's insistence, cause a patient who is psychically normal to accuse himself falsely of sexual misdemeanours - such an idea may safely be disregarded as an imaginary danger.

If one proceeds in this manner with one's patients, one also gains the conviction that, so far as the theory of the sexual aetiology of neurasthenia is concerned, there are no negative cases. In my mind, at least, the conviction has become so certain that where an interrogation has shown a negative result, I have turned this to account too for diagnostic purposes. I have told myself, that is, that such a case cannot be one of neurasthenia. In this way I have been led in several instances to assume the presence of progressive paralysis instead of neurasthenia, because I had not succeeded in establishing the fact - a fact that was necessary for my theory - that the patient indulged very freely in masturbation; and the further course of those cases later confirmed my view. In another instance the patient, who exhibited no clear organic changes, complained of intracranial pressure, headaches and dyspepsia, but countered my suspicions about his sexual life straightforwardly and with unshaken certainty; and the possibility occurred to me that he might have a latent suppuration in one of his nasal sinuses. A specialist colleague of mine confirmed this inference I had made from the negative sexual results of my interrogation, by removing the pus from the patient's antrum and relieving him of his ailments.

The appearance of there nevertheless being 'negative cases' can arise in another way as well. Sometimes an interrogation discloses the presence of a normal sexual life in a patient whose neurosis, on a superficial view, does in fact closely resemble neurasthenia or anxiety neurosis. But a more deep -going investigation regularly reveals the true state of affairs. Behind such cases, which have been taken for neurasthenia, there lies a psychoneurosis - hysteria or obsessional neurosis. Hysteria in especial, which imitates so many organic affections, can easily assume the appearance of one of the 'actual neuroses' by elevating the latter's symptoms into hysterical ones. Such hysterias in the form of neurasthenia are not even very rare. Falling back on psychoneurosis when a case of neurasthenia shows a negative sexual result, is, however, no cheap way out of the difficulty; the proof that we are right is to be obtained by the method which alone unmasks hysteria with certainty - the method of psycho-analysis, to which we shall refer presently.

There may perhaps be some, however, who are quite willing to recognize the sexual aetiology in their neurasthenic patients, but who nevertheless blame it as one-sidedness if they are not asked to pay attention as well to the other factors which are always mentioned by the authorities as causes of neurasthenia. Now it would never occur to me to substitute a sexual aetiology in neuroses for every other aetiology, and so to assert that the latter have no operative force. This would be a misunderstanding. What I think is rather that in addition to all the familiar aetiological factors which have been recognized - and probably correctly so - by the authorities as leading to neurasthenia, the sexual factors, which have not hitherto been sufficiently appreciated, should also be taken into account. In my opinion, however, these sexual factors deserve to be given a special place in the aetiological series. For they alone are never absent in any case of neurasthenia, they alone are capable of producing the neurosis without any further assistance, so that those other factors seem to be reduced to the role of an auxiliary and supplementary aetiology, and they alone allow the physician to recognize firm relations between their manifold nature and the multiplicity of the clinical pictures. If, on the other hand, I group together all the patients who have ostensibly become neurasthenic from overwork, emotional agitation, as an after-effect of typhoid fever, and so on, they show me nothing in common in their symptoms. The nature of their aetiology gives me no idea of what kind of symptoms to expect, any more than, conversely, does the clinical picture they present enable me to infer what aetiology is at work in them.

The sexual causes, too, are the ones which most readily offer the physician a foothold for his therapeutic influence. Heredity is no doubt an important factor, when it is present; it enables a strong pathological effect to come about where otherwise only a very slight one would have resulted. But heredity is inaccessible to the physician's influence; everyone is born with his own hereditary tendencies to illness, and we can do nothing to change them. Nor should we forget that it is precisely in regard to the aetiology of the neurasthenias that we must necessarily deny the first place to heredity. Neurasthenia (in both its forms) is one of those affections which anyone may easily acquire without having any hereditary taint. If it were otherwise, the enormous increase in neurasthenia, of which all the authorities complain, would be unthinkable. In what concerns civilization, among whose sins people so often include responsibility for neurasthenia, these authorities may indeed be right (although the way in which this comes about is probably quite different from what they imagine). Yet the state of our civilization is, once again, something that is unalterable for the individual. Moreover this factor, being common to all the members of the same society, can never explain the fact of selectivity in the incidence of the illness. The physician who is not neurasthenic is exposed to the same influence of an allegedly detrimental civilization as the neurasthenic patient whom he has to treat. Subject to these limitations, the factors of exhaustion retain their significance. But the element of 'overwork', which physicians are so fond of producing to their patients as the cause of their neurosis, is too often unduly misused. It is quite true that anyone who, owing to sexual noxae, has made himself disposed to neurasthenia, tolerates intellectual work and the psychical exigencies of life badly; but no one ever becomes neurotic through work or excitement alone. Intellectual work is rather a protection against falling ill of neurasthenia; it is precisely the most unremitting intellectual workers who remain exempt from neurasthenia, and what neurasthenics complain of as 'overwork that is making them ill' does not as a rule deserve to be called 'intellectual work' at all, either in its quality or quantity. Physicians will have to become accustomed to explaining to an office-worker who has been 'overworked' at his desk or to a housewife for whom her domestic activities have become too heavy, that they have fallen ill, not because they have tried to carry out duties which are in fact easily performed by a civilized brain, but because all the while they have been grossly neglecting and damaging their sexual life.

Furthermore, it is only the sexual aetiology which makes it possible for us to understand all the details of the clinical history of neurasthenics, the mysterious improvements in the middle of the course of the illness and the equally incomprehensible deteriorations, both of which are usually related by doctors and patients to whatever treatment has been adopted. In my records, which include more than two hundred cases, there is, for instance, the story of a man who, when the treatment prescribed by his family physician had done him no good, went to Pastor Kneipp and for a year after being treated by him showed an extraordinary improvement in the middle of his illness. But when, a year later, his symptoms grew worse once more and he again went to Wörishofen for help, the second treatment was unsuccessful. A glance into the patient's family record solved the double riddle. Six and a half months after his first return from Wörishofen his wife bore him a child. This meant that he had left her at the beginning of a pregnancy of which he was not yet aware; after his return he was able to practise *natural* intercourse with her. At the close of this period, which had a curative effect on him, his neurosis was started up afresh by his once more resorting to coitus interruptus; the second treatment was bound to prove a failure, since this pregnancy of his wife's remained her last.

There was a similar case, in which, once again, the treatment had an unexpected effect which called for an explanation. This case turned out to be still more instructive, for it exhibited a puzzling alternation in the symptoms of the neurosis. A young neurotic patient had been sent by his physician to a reputable hydropathic establishment on account of a typical neurasthenia. There his condition steadily improved at first, so that there was every prospect that he would be discharged as a grateful disciple of hydrotherapy. But in the sixth week a complete change occurred; the patient 'could no longer tolerate the water', became more and more nervous, and finally left the establishment after two more weeks, uncured and dissatisfied. When he complained to me about this therapeutic fraud I asked him a few questions about the symptoms which had overtaken him in the middle of the treatment. Curiously enough, a complete change had come over them. He had *entered* the sanatorium with intracranial pressure, fatigue and dyspepsia; what had troubled him *during* the treatment were excitement, attacks of dyspnoea, vertigo in walking, and disturbances of sleep. I was now able to say to him: 'You are doing hydrotherapy an injustice. As you yourself very well knew, you fell ill as a result of long-continued masturbation. In the sanatorium you gave up this form of satisfaction, and therefore you quickly recovered. When you felt well, however, you unwisely sought to have relations with a lady - a fellow-patient, let us suppose - which could only lead to excitement without normal satisfaction. The beautiful walks in the neighbourhood of the establishment gave you ample opportunity for this. It was this relationship, not a sudden inability to tolerate hydrotherapy, which caused you to fall ill once more. Moreover, your present state of health leads me to conclude that you are continuing this relationship here in town as well.' I can assure my readers that the patient confirmed what I said, point by point.

The present treatment of neurasthenia - which is, perhaps, carried out most successfully in hydropathic establishments - has as its aim the amelioration of the nervous condition by means of two factors : shielding the patient and strengthening him. I have nothing to say against such a method of treatment, except that it takes no account of the circumstances of the patient's sexual life. According to my experience, it is highly desirable that the medical directors of such establishments should become properly aware that they are dealing, not with victims of civilization or heredity, but - *sit venia verbo* - with people who are crippled in sexuality. They would then, on the one hand, be more easily able to account for their successes as well as their failures; and, on the other, they would achieve new successes which, till now, have been at the mercy of chance or of the patient's unguided behaviour. If we take a neurasthenic woman, suffering from anxiety, away from her home and send her to a hydropathic establishment, and if there, freed from all duties, she is made to bathe and take exercise and eat plenty of food, we shall certainly be inclined to think that the improvement - often a brilliant one - which is achieved in a few weeks or months is due to the rest which she has enjoyed and to the invigorating effects of hydrotherapy. That may be so: but we are overlooking the fact that her removal from home also entails an interruption of marital intercourse, and that it is only the temporary elimination of this pathogenic cause which makes it possible for her to recover under favourable treatment. Neglect of this aetiological point of view brings its subsequent revenge, when what seemed such a gratifying cure turns out to be a very transitory one. Soon after the patient has returned to ordinary life the symptoms of the complaint appear once more and oblige him either to spend a part of his existence unproductively from time to time in establishments of this kind or to direct his hopes of recovery elsewhere. It is therefore clear that with neurasthenia the therapeutic problems must be attacked, not in hydropathic institutions but within the framework of the patient's life.

In other cases our aetiological theory can help the physician in charge of the institution by throwing light on the source of failures which occur in the institution itself, and can suggest to him means of avoiding them. Masturbation is far commoner among grown-up girls and mature men than is generally supposed, and it has a harmful effect not only by producing neurasthenic symptoms, but also because it keeps the patients under the weight of what they feel to be a disgraceful secret. Physicians who are not accustomed to translate neurasthenia into masturbation account for the patient's pathological state by referring it to some catchword like anaemia, undernourishment, overwork, etc., and then expect to cure him by applying a therapy devised against those conditions. To their astonishment, however, periods of improvement in him alternate with periods in which all his symptoms grow worse and are accompanied by severe depression. The outcome of such a treatment is, in general, doubtful. If physicians knew that all the while the patient was struggling against his sexual habit and that he was in despair because he had once more been obliged to give way to it, if they understood how to win his secret from him, to make it less serious in his eyes and to support him in his fight against the habit, then the success of their therapeutic efforts might in this way well be assured.

To break the patient of the habit of masturbating is only one of the new therapeutic tasks which are imposed on the physician who takes the sexual aetiology of the neurosis into account; and it seems that precisely this task, like the cure of any other addiction, can only be carried out in an institution and under medical supervision. Left to himself, the masturbator is accustomed, whenever something happens that depresses him, to return to his convenient form of satisfaction. Medical treatment, in this instance, can have no other aim than to lead the neurasthenic, who has now recovered his strength, back to normal sexual intercourse. For sexual need, when once it has been aroused and has been satisfied for any length of time, can no longer be silenced; it can only be displaced along another path. Incidentally, the same thing applies to all treatments for breaking an addiction. Their success will only be an apparent one, so long as the physician contents himself with withdrawing the narcotic substance from his patients, without troubling about the source from which their imperative need for it springs. 'Habit' is a mere form of words, without any explanatory value. Not everyone who has occasion to take morphia, cocaine, chloral hydrate, and so on, for a period, acquires in this way an 'addiction' to them. Closer enquiry usually shows that these narcotics are meant to serve - directly or indirectly - as a substitute for a lack of sexual satisfaction; and whenever normal sexual life can no longer be re-established, we can count with certainty on the patient's relapse.

Another task is set to the physician by the aetiology of anxiety neurosis. It consists in inducing the patient to give up all detrimental forms of sexual intercourse and to adopt normal sexual relations. This duty, it will be understood, falls primarily on the patient's trusted physician - his family doctor; and he will do his patient a serious injury if he regards himself as too respectable to intervene in this field.

Since in these instances it is most often a question of a married couple, the physician's efforts at once encounter Malthusian plans for limiting the number of conceptions in marriage. There seems to me no doubt that such proposals are gaining ground more and more among our middle classes. I have come across some couples who have already begun practising methods for preventing conception as soon as they have had their first child, and others whose sexual intercourse was from their wedding-night designed to comply with that purpose. The problem of Malthusianism is far-reaching and complicated, and I have no intention of handling it here in the exhaustive manner which would actually be necessary for the treatment of neuroses. I shall only consider what attitude a physician who recognizes the sexual aetiology of the neuroses had best take up towards the problem.

The worst thing he can do is obviously - under whatever pretext - to try to ignore it. Nothing that is necessary can be beneath my dignity as a doctor; and it is necessary to give a married couple who contemplate limiting the number of their offspring the assistance of one's medical advice if one does not want to expose one or both of them to a neurosis. It cannot be denied that in any marriage Malthusian preventive measures will become necessary at some time or other; and, from a theoretical point of view, it would be one of the greatest triumphs of humanity, one of the most tangible liberations from the constraints of nature to which mankind is subject, if we could succeed in raising the responsible act of procreating children to the level of a deliberate and intentional activity and in freeing it from its entanglement with the necessary satisfaction of a natural need.

A perspicacious physician will therefore take it upon himself to decide under what conditions the use of measures for preventing conception are justified, and, among those measures, he will have to separate the harmful from the harmless ones. Everything is harmful that hinders the occurrence of satisfaction. But, as we know, we possess at present no method of preventing conception which fulfils every legitimate requirement - that is, which is certain and convenient, which does not diminish the sensation of pleasure during coitus and which does not wound the woman's sensibilities. This sets physicians a practical task to the solution of which they could bend their energies with rewarding results. Whoever fills in this lacuna in our medical technique will have preserved the enjoyment of life and maintained the health of numberless people; though, it is true, he will also have paved the way for a drastic change in our social conditions.

This does not exhaust the possibilities which flow from a recognition of the sexual aetiology of the neuroses. The main benefit which we obtain from it for neurasthenics lies in the sphere of prophylaxis. If masturbation is the cause of neurasthenia in youth, and if, later on, it acquires aetiological significance for anxiety neurosis as well, by reason of the reduction of potency which it brings about, then the prevention of masturbation in both sexes is a task that deserves more attention than it has hitherto received. When we reflect upon all the injuries, both the grosser and the finer ones, which proceed from neurasthenia - a disorder which we are told is growing more and more prevalent - we see that it is positively a matter of public interest that *men should enter upon sexual relations with full potency*. In matters of prophylaxis, however, the individual is relatively helpless. The whole community must become interested in the matter and give their assent to the creation of generally acceptable regulations. At present we are still far removed from such a state of affairs which would promise relief, and it is for this reason that we may with justice regard civilization, too, as responsible for the spread of neurasthenia. Much would have to be changed. The resistance of a generation of physicians who can no longer remember their own youth must be broken down; the pride of fathers, who are unwilling to descend to the level of humanity in their children's eyes, must be overcome; and the unreasonable prudery of mothers must be combated - the mothers who at present look upon it as an incomprehensible and undeserved stroke of fate that '*their* children should have been the ones to become neurotic'. But above all, a place must be created in public opinion for the discussion of the problems of sexual life. It will have to become possible to talk about these things without being stamped as a trouble-maker or as a person who makes capital out of the lower instincts. And so here, too, there is enough work left to do for the next hundred years - in which our civilization will have to learn to come to terms with the claims of our sexuality.

The value of making a correct diagnostic separation of the psychoneuroses from neurasthenia is also shown by the fact that the psychoneuroses call for a different practical assessment and for special therapeutic measures. They make their appearance as a result of two kinds of determinants, either independently or in the train of the 'actual neuroses' (neurasthenia and anxiety neurosis). In the latter case we are dealing with a new type of neurosis - incidentally, a very frequent one - a mixed neurosis. The aetiology of the 'actual neuroses' has become an auxiliary aetiology of the psychoneuroses. A clinical picture arises in which, let us say, anxiety neurosis predominates but which also contains traits of genuine neurasthenia, hysteria and obsessional neurosis. When confronted with a mixture of this kind, we shall nevertheless not be wise to give up separating out the clinical pictures proper to each neurotic illness; for after all it is not difficult to explain the case to oneself in the following manner. The predominant place taken by the anxiety neurosis shows that the illness has come into being under the aetiological influence of an 'actual' sexual noxa. But the person concerned was, apart from that, disposed to one or more of the psychoneuroses owing to a special aetiology and would at some time or other have fallen ill of a psychoneurosis either spontaneously or with the advent of some other weakening factor. In this way the auxiliary aetiology for the psychoneurosis which is still lacking is supplied by the actual aetiology of the anxiety neurosis.

For such cases it has quite correctly come to be the therapeutic practice to disregard the psychoneurotic components in the clinical picture and to treat the 'actual neurosis' exclusively. In very many cases it is possible to overcome the neurosis as well which it has brought along with it, provided that the neurasthenia is effectively dealt with. But a different view must be taken in those cases of psychoneurosis which either appear spontaneously or remain behind as an independent entity after an illness composed of neurasthenia and psychoneurosis has run its course. When I speak of a 'spontaneous' appearance of a psychoneurosis, I do not mean that anamnestic investigation shows us no aetiological element whatever. It may do so, no doubt; but it may also happen that our attention is directed to some indifferent factor - an emotional state, an enfeeblement owing to physical illness, and so on. It must, however, be borne in mind in all these cases that the true aetiology of the psychoneuroses does not lie in such precipitating causes, but remains beyond the reach of ordinary anamnestic examination.

As we know, it is in an attempt to bridge this gap that the assumption has been made of a special neuropathic disposition (which, incidentally, if it existed, would not leave much hope of success for the treatment of such pathological conditions). The neuropathic disposition itself is regarded as a sign of a general degeneracy, and thus this convenient technical term has come to be superabundantly used against the wretched patients whom the doctors are quite incapable of helping. Fortunately, the state of affairs is different. The neuropathic disposition does no doubt exist, but I must deny that it suffices for the creation of a psychoneurosis. I must further deny that the conjunction of a neuropathic disposition with precipitating causes occurring in later life constitutes an adequate aetiology of the psychoneuroses. In tracing back the vicissitudes of an individual's illness to the experiences of his ancestors, we have gone too far; we have forgotten that between his conception and his maturity there lies a long and important period of life - his childhood - in which the seeds of later illness may be acquired. And that- is what in fact happens with a psychoneurosis. Its true aetiology is to be found in childhood experiences, and, once again - and exclusively - in impressions concerned with sexual life. We do wrong to ignore the sexual life of children entirely; in my experience, children are capable of every psychical sexual activity, and many somatic sexual ones as well. Just as the whole human sexual apparatus is not comprised in the external genitals and the two reproductive glands, so human sexual life does not begin only with puberty, as on a rough inspection it may appear to do. Nevertheless it is true that the organization and evolution of the human species strives to avoid any great degree of sexual activity during childhood. It seems that in man the sexual instinctual forces are meant to be stored up so that, on their release at puberty, they may serve great cultural ends. (W. Fliess.) Consideration of this sort may make it possible to understand why the sexual experiences of childhood are bound to have a pathogenic effect. But they produce their effect only to a very slight degree at the time at which they occur; what is far more important is their *deferred* effect, which can only take place at later periods of growth. This deferred effect originates - as it can do in no other way - in the psychical traces which have been left behind by infantile sexual experiences. During the interval between the experiences of those impressions and their reproduction (or rather, the reinforcement of the libidinal impulses which proceed from them), not only the somatic sexual apparatus but the psychical apparatus as well has undergone an important development; and thus it is that the influence of these earlier sexual experiences now leads to an abnormal psychical reaction, and psychopathological structures come into existence.

I can do no more in these brief hints than mention the chief factors on which the theory of the psychoneuroses is based: the deferred nature of the effect and the infantile state of the sexual apparatus and of the mental instrument. To reach a true understanding of the mechanism by which the psychoneuroses come about, a more extended exposition would be necessary. Above all, it would be indispensable to put forward as worthy of belief certain hypotheses, which seem to me to be new, about the composition and mode of operation of the psychical apparatus. In a book on the interpretation of dreams on which I am now engaged I shall find occasion to touch upon those fundamental elements of a psychology of the neuroses. For dreams belong to the same set of psychopathological structures as hysterical *idées fixes*, obsessions, and delusions.

Since the manifestations of the psychoneuroses arise from the deferred action of unconscious psychical traces, they are accessible to psychotherapy. But in this case the therapy must pursue paths other than the only one so far followed of suggestion with or without hypnosis. Basing myself on the 'cathartic' method introduced by Josef Breuer, I have in recent years almost completely worked out a therapeutic procedure which I propose to describe as '*psycho-analytic*'. I owe a great number of successes to it, and I hope I may be able further to increase its effectiveness considerably. The first accounts of the technique and scope of this method were given in *Studies on Hysteria*, written jointly with Breuer and published in 1895. Since then a good deal, as I think I may say, has been altered for the better. Whereas at that time we modestly declared that we could undertake only to remove the symptoms of hysteria, not to cure hysteria itself, this distinction has since come to seem to me without substance, so that there is a prospect of a genuine cure of hysteria and obsessions. It is therefore with very lively interest that I have read in the publications of colleagues that 'in this case the ingenious procedure devised by Breuer and Freud has failed', or that 'the method has not performed what it seemed to promise'. This gave me something of the feelings of a man who reads his own obituary in the paper, but who is able to reassure himself by his better knowledge of the facts. For the method is so difficult that it has quite definitely to be learned; and I cannot recall that a single one of my critics has expressed a wish to learn it from me. Nor do I believe that, like me, they have occupied themselves with it intensely enough to have been able to discover it for themselves. The remarks in the *Studies on Hysteria* are totally inadequate to enable a reader to master the technique, nor are they in any way intended to give any such complete instruction.

Psycho-analytic therapy is not at present applicable to all cases. It has, to my knowledge, the following limitations. It demands a certain degree of maturity and understanding in the patient and is therefore not suited for the young or for adults who are feeble-minded or uneducated. It also fails with people who are very advanced in years, because, owing to the accumulation of material in them, it would take up so much time that by the end of the treatment they would have reached a period of life in which value is no longer attached to nervous health. Finally, the treatment is only possible if the patient has a normal psychical state from which the pathological material can be mastered from which to work i.e. a relatively normal ego. During a condition of hysterical confusion, or an interpolated mania or melancholia, nothing can be effected by psycho-analytic means. Such cases can nevertheless be treated by analysis after the violent manifestations have been quieted by the usual measures. In actual practice, chronic cases of psychoneurosis are altogether more amenable to the method than cases with acute crises, in which the greatest stress is naturally laid on the speed with which the crises can be dealt with. For this reason, the most favourable field of work for this new therapy is offered by hysterical phobias and the various forms of obsessional neurosis.

That the method is confined within these limits is to a large extent explained by the circumstances in which I had to work it out. My material does in fact consist of chronic nervous cases derived from the more educated classes. I think it very probable that supplementary methods may be devised for treating children and the public who go for assistance to hospitals. I ought also to say that up to the present I have tried my treatment exclusively on *severe* cases of hysteria and obsessional neurosis; I cannot tell how it would turn out with those mild cases which, to all appearance at least, are cured by some unspecific kind of treatment lasting for a few months. It will readily be understood that a new therapy which calls for many sacrifices can only reckon on obtaining patients who have already tried the generally accepted methods without success, or whose condition has justified the inference that they could expect nothing from these supposedly more convenient and shorter therapeutic procedures. Thus it happened that I was obliged to tackle the hardest tasks straightaway with an imperfect instrument. The test has proved all the more convincing.

The main difficulties which still stand in the way of the psycho-analytic method of cure. It is no more than a necessary corollary to this complete ignorance that doctors consider themselves justified in using the most unfounded assurances for the consolation of their patients or in order to induce them to adopt therapeutic measures. 'Come to my sanatorium for six weeks', they will say, 'and you will get rid of your symptoms' (travel anxiety, obsessions, and so on). Sanatoria are, it is true, indispensable for calming acute attacks that may arise in the course of a psychoneurosis by diverting the patient's attention, nursing him and taking care of him. But towards removing chronic conditions they achieve precisely nothing: and the superior sanatoria, which are supposed to be conducted on scientific lines, do no more than the ordinary hydropathic establishments.

It would be more dignified as well as more helpful to the patient - who, after all, has to come to terms with his ailments - for the doctor to tell the truth, as he knows it from his daily practice. The psychoneuroses as a genus are by no means mild illnesses. When hysteria sets in, no one can foretell when it will come to an end. We mostly comfort ourselves with the vain prophecy that 'one day it will suddenly disappear'. Recovery often enough turns out to be merely an agreement to mutual toleration between the sick part of the patient and the healthy part; or it is the result of the transformation of a symptom into a phobia. A girl's hysteria, calmed down with difficulty, revives in her as a wife after the short interruption of young married happiness. The only difference is that another person, the husband, is now driven by his own interests to keep silence about her condition. Even if an illness of this kind leads to no manifest incapacity on the patients' part to carry on their life, it nearly always prevents free unfolding of their mental powers. Obsessions recur throughout their lives; and phobias and other restrictions upon the will have hitherto been unamenable to treatment of any kind. All this is kept from the knowledge of the layman. The father of a hysterical girl is consequently horrified if, for instance, he is asked to agree to her being given a year's treatment, when she has perhaps only been ill for a few months. The layman is, as it were, deeply convinced in himself that all these psychoneuroses are unnecessary; so he has no patience with the processes of the illness and no readiness to make sacrifices for its treatment. If, in face of a case of typhus which lasts three weeks, or of a broken leg which takes six months to mend, he adopts a more understanding attitude, and if, as soon as his child shows the first signs of a curvature of the spine, he finds it reasonable that orthopaedic treatment should be carried on over several years, the difference in his behaviour is due to the better knowledge on the part of the physicians who pass on their knowledge honestly to the layman. Honesty on the part of the physician and willing acquiescence on the part of the layman will be established for the neuroses too, as soon as an insight into the nature of those affections becomes common property in the medical world. Radical treatment of these disorders will no doubt always require special training and will be incompatible with other kinds of medical activity. On the other hand, this class of physicians, which will, I believe, be a large one in the future, has the prospect of achieving noteworthy results and of obtaining a satisfying insight into the mental life of mankind.

THE PSYCHICAL MECHANISM OF FORGETFULNESS
(1898)

Intentionally left blank

THE PSYCHICAL MECHANISM OF FORGETFULNESS

The phenomenon of forgetfulness, which I should like to describe and then go on to explain in this paper, has doubtless been experienced by everyone in himself or been observed by him in others. It affects in particular the use of proper names - *nomen propria* - and it manifests itself in the following manner. In the middle of carrying on a conversation we find ourselves obliged to confess to the person we are talking to that we cannot hit on a name we wanted to mention at that moment, and we are forced to ask for his - usually ineffectual - help. 'What is his name? I know it so well. It's on the tip of my tongue. Just this minute it's escaped me.' An unmistakable feeling of irritation, similar to that which accompanies motor aphasia, now attends our further efforts to find the name, which we feel we had in our head only a moment before. In appropriate instances two accompanying features deserve our notice. First, an energetic deliberate concentration of the function which we call attention proves powerless, however long it is continued, to find the lost name. Secondly, in place of the name we are looking for, another name promptly appears, which we recognize as incorrect and reject, but which persists in coming back. Or else, instead of a substituted name, we find in our memory a single letter or syllable, which we. We say, for instance: 'It begins with a "B".' If we finally succeed, in one way or another, in discovering what the name is, we find in the great majority of cases that it does not begin with a 'B' and does not in fact contain the letter 'B' at all.

The best procedure for getting hold of the missing name is, as is generally known, 'not to think of it' - that is, to divert from the task that part of the attention over which one has voluntary control. After a while, the missing name 'shoots' into one's mind; one cannot prevent oneself from calling it out aloud - to the great astonishment of one's companion, who has already forgotten the episode and who has in any case only taken very little interest in the speaker's efforts. 'Really,' he is apt to say, 'it makes no difference *what* the man is called; only go on with your story.' The whole of the time until the matter is cleared up, and even after the intentional diversion, one feels preoccupied to a degree which cannot in fact be explained by the amount of interest possessed by the whole affair.¹

In a few cases which I have myself experienced of forgetting names in this way, I have succeeded, by means of psychical analysis, in accounting to myself for the chain of events; and I shall now describe in detail the simplest and clearest case of this kind.

During my summer holidays I once went for a carriage drive from the lovely city of Ragusa to a town nearby in Herzegovina. Conversation with my companion centred, as was natural, round the condition of the two countries (Bosnia and Herzegovina) and the character of their inhabitants. I talked about the various peculiarities of the Turks living there, as I had heard them described years before by a friend and colleague who had lived among them as a doctor for many years. A little later, our conversation turned to the subject of Italy and of pictures, and I had occasion to recommend my companion strongly to visit Orvieto some time, in order to see the frescoes there of the end of the world and the Last Judgement, with which one of the chapels in the cathedral had been decorated by a great artist. But the artist's name escaped me and I could not recall it. I exerted my powers of recollection, made all the details of the day I spent in Orvieto pass before my memory and convinced myself that not the smallest part of it had been obliterated or become indistinct. On the contrary, I was able to conjure up the pictures with greater sensory vividness than is usual with me. I saw before my eyes with especial sharpness the artist's self-portrait - with a serious face and folded hands - which he has put in a corner of one of the pictures, next to the portrait of his predecessor in the work, Fra Angelico da Fiesole; but the artist's name, ordinarily so familiar to me, remained obstinately in hiding, nor could my travelling companion help me out. My continued efforts met with no success beyond bringing up the names of two other artists, who I knew could not be the right ones. These were *Botticelli* and, in the second place, *Boltraffio*.² The repetition of the sound 'Bo' in the two substitutive names might perhaps have led a novice to suppose that it belonged to the missing name as well, but I took good care to steer clear of that expectation.

¹ Nor by any feeling of displeasure one may have at being inhibited in a psychical act.

² The first of these names was very familiar to me; the second, on the other hand, I hardly knew.

Since I had no access to any reference books on my journey, I had for several days to put up with this lapse of memory and with the inner torment associated with it which recurred at frequent intervals each day, until I fell in with a cultivated Italian who freed me from it by telling me the name: *Signorelli*. I was myself able to add the artist's *first* name, *Luca*. Soon my ultra-clear memory of the master's features, as depicted in his portrait, faded away.

What influences had led me to forget the name *Signorelli* which was so familiar to me and which is so easily impressed on the memory? And what paths had led to its replacement by the names *Botticelli* and *Boltraffio*? A short excursion back into the circumstances in which the forgetting had taken place sufficed to throw a light on both questions.

Shortly before I had come to the subject of the frescoes in the cathedral at Orvieto, I had been telling my travelling-companion something I had heard from my colleague years ago about the Turks in Bosnia. They treat doctors with special respect and they show, in marked contrast to our own people, an attitude of resignation towards the dispensations of fate. If the doctor has to inform the father of a family that one of his relatives is about to die, his reply is: '*Herr*, what is there to be said? If he could be saved, I know you would help him.' Another recollection lay in my memory close to this story. The same colleague had told me what overriding importance these Bosnians attached to sexual enjoyments. One of his patients said to him once: '*Herr*, you must know, that if *that* comes to an end then life is of no value.' At the time, it seemed to the doctor and me that the two character-traits of the Bosnian people illustrated by this could be assumed to be intimately connected with each other. But when I remembered these stories on my drive into Herzegovina, I suppressed the second one, in which the subject of sexuality was touched on. It was soon after this that the name *Signorelli* escaped me and that the names *Botticelli* and *Boltraffio* appeared as substitutes.

The influence which had made the name *Signorelli* inaccessible to memory, or, as I am accustomed to say, had 'repressed' it, could only proceed from the story I had suppressed about the value set on death and sexual enjoyment. If that was so, we ought to be able to discover the intermediate ideas which had served to connect the two themes. The affinity between their *content* - in the one case, the Last Judgement, 'Doomsday', and in the other, death and sexuality- seems to be very slight; and since the matter concerned the repression from memory of a *name*, it was on the face of it probable that the connection was between one name and another. Now, '*Signor*' means '*Herr*', and the '*Herr*' is also present in the name '*Herzegovina*'. Moreover it was certainly not without relevance that both the patients' remarks which I was to recall contained a '*Herr*' as a form of address to the doctor. The translation of '*Signor*' into '*Herr*' was therefore the means by which the story that I had suppressed had drawn after it into repression the name I was looking for. The whole process was clearly made easier by the fact that during the last few days in Ragusa I had been speaking Italian continually - that is, that I had become accustomed to translating German into Italian in my head.¹

When I tried to recover the name of the artist, to bring it back out of repression, the influence of the tie which the name had entered into in the meantime inevitably made itself felt. I did find an artist's name, but not the right one. It was a displaced name, and the line of displacement was laid down by the names that were contained in the repressed topic. '*Botticelli*' contains the same final syllables as '*Signorelli*'; the final syllables - which, unlike the first part of the word, '*Signor*', could not make a direct connection with the name '*Herzegovina*' - had therefore returned; but the influence of the name '*Bosnia*', which is regularly associated with the name '*Herzegovina*', had shown itself by directing the substitution to two artists' names which began with the same syllable '*Bo*': '*Botticelli*' and then '*Boltraffio*'. The finding of the name '*Signorelli*' is thus seen to have been interfered with by the topic which lay behind it, in which the names '*Bosnia*' and '*Herzegovina*' appear.

¹ 'A far-fetched, forced explanation', it will be said. This impression to establish a connection with what is not suppressed; and for this purpose it does not scorn even the path of external association. There is the same 'forced' situation when rhymes have to be made.

For this topic to have been able to produce such effects it is not enough that I should have suppressed it once in conversation - an event brought about by chance motives. We must assume rather that the topic itself was also intimately bound up with trains of thought which were in a state of repression in me - that is, with trains of thought which, in spite of the intensity of the interest taken in them, were meeting with a resistance that was keeping them from being worked over by a particular psychological agency and thus from becoming conscious. That this was really true at that time of the topic of 'death and sexuality' I have plenty of evidence, which I need not bring up here, derived from my own self-investigation. But I may draw attention to one consequence of these repressed thoughts. Experience has taught me to require that every psychological product shall be fully elucidated and even overdetermined. Accordingly, it seemed to me that the second substitutive name, 'Boltraffio', called for a further determination; for so far only its initial letters had been accounted for, by their assonance with 'Bosnia'. I now recollected that these repressed thoughts had never engrossed me more than they had a few weeks before after I had received a certain piece of news. The place where the news reached me was called 'Trafoi' and this name is too much like the second half of the name 'Boltraffio' not to have had a determining effect on my choice of the latter. In the following small schematic diagram, I have attempted to reproduce the relations which have now been brought to light.

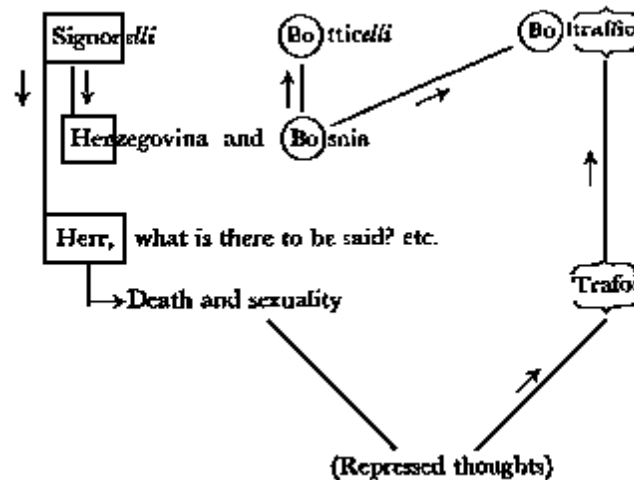

Fig. 1

It is perhaps not without interest for its own sake to be able to see into the history of a psychological event of this kind, which is among the most trivial disturbances that can affect the control of the psychological apparatus and which is compatible with an otherwise untroubled state of psychological health. But the example elucidated here receives an immensely added interest when we learn that it may serve as nothing more nor less than a model for the pathological processes to which the psychological symptoms of the psychoneuroses - hysteria, obsessions and paranoia - owe their origin. In both cases we find the same elements and the same play of forces between those elements. In the same manner as here and by means of similar superficial associations, a repressed train of thought takes possession in neuroses of an innocent recent impression and draws it down with itself into repression. The same mechanism which causes the substitute names 'Botticelli' and 'Boltraffio' to emerge from 'Signorelli' (a substitution by means of intermediate or compromise ideas) also governs the formation of obsessional thoughts and paranoid paramnesias. Again, we have seen that such cases of forgetfulness have the characteristic of liberating continuous unpleasure till the moment the problem is solved - a characteristic which is unintelligible apart from this, and something which was in fact unintelligible to the person I was talking to; but there is a complete analogy to it in the way in which collections of repressed thoughts attach their capacity for producing affect to some symptom whose psychological content seems to our judgement totally unsuited to such a liberation of affect. Finally, the resolution of the whole tension by a communication of the correct name from an external quarter is itself a good example of the efficacy of psycho-analytic therapy, which aims at correcting the repressions and displacements and which removes the symptoms by re-instating the genuine psychological object.

Among the various factors, therefore, which contribute to a failure in recollection or a loss of memory, the part played by repression must not be overlooked; and it can be demonstrated not only in neurotics but (in a manner that is qualitatively the same) in normal people as well. It may be asserted quite generally that the ease (and ultimately the faithfulness, too) with which a given impression is awakened in the memory depends not only on the psychological constitution of the individual, the strength of the impression when it was fresh, the interest directed towards it at the time, the psychological constellation at the present time, the interest that is *now* devoted to its awakening, the connections into which the impression has been drawn, and so on - not only on such things but also on the favourable or unfavourable attitude of a particular psychological factor which refuses to reproduce anything that might liberate unpleasure, or that might subsequently lead to the liberation of unpleasure. Thus the function of memory, which we like to regard as an archive open to anyone who is curious, is in this way subjected to restriction by a trend of the will, just as is any part of our activity directed to the external world. Half the secret of hysterical amnesia is uncovered when we say that hysterical people do not know what they do not *want* to know; and psycho-analytic treatment, which endeavours to fill up such gaps of memory in the course of its work, leads us to the discovery that the bringing back of those lost memories is opposed by a certain resistance which has to be counterbalanced by work proportionate to its magnitude. In the case of psychological processes which are on the whole normal, it cannot, of course, be claimed that the influence of this one-sided factor in the revival of memories in any way regularly overcomes all the other factors that must be taken into account.¹

¹ It would be a mistake to believe that the mechanism which I have brought to light in these pages only operates in rare cases. It is, on the contrary, a very common one. On one occasion, for instance, when I was meaning to describe the same small incident to a colleague of mine, the name of my authority for the stories about Bosnia suddenly escaped me. The reason for this was as follows. Just before, I had been playing cards. My authority was called Pick. Now 'Pick' and 'Herz' are two of the four suits in the pack. Moreover the two words were connected by an anecdote in which this same person pointed to himself and said: 'I'm not called "Herz", but "Pick".' 'Herz' appears in the name 'Herzegovina' and the heart itself, as a sick bodily organ, played a part in the thoughts I have described as having been repressed.

In connection with the tendentious nature of our remembering and forgetting, I not long ago experienced an instructive example - instructive because of what it betrayed - of which I should like to add an account here. I was intending to pay a twenty-four-hour visit to a friend of mine who unfortunately lives very far away, and I was full of the things I was going to tell him. But before this I felt under an obligation to call on a family of my acquaintance in Vienna, one of whose members had moved to the town in question, so as to take their greetings and messages with me to the absent relative. They told me the name of the *pension* in which he lived, and also the name of the street and the number of the house, and, in view of my bad memory, wrote the address on a card, which I put in my wallet. The next day, when I had arrived at my friend's, I began: 'I've only one duty to carry out that may interfere with our being together; it's a call, and it shall be the first thing I do. The address is in my wallet.' To my astonishment, however, it was not to be found there. So now I had to fall back on my memory, after all. My memory for names is not particularly good, but it is incomparably better than for figures and numbers. I may have been paying medical visits at a certain house for a year on end, and yet, if I should have to be driven there by a cab driver, I should have difficulty in remembering the number of the house. But in this case I had taken special note of the house number; it was ultra-clear, as if to jeer at me - for no trace remained in my recollection of the name of the *pension* or the street. I had forgotten all the data in the address which might have served as a starting - point for discovering the *pension*; and, quite against my usual habit, I had retained the number of the house, which was useless for the purpose. In consequence, I was unable to make the call. I was consoled remarkably quickly, and I devoted myself entirely to my friend. When I was back again in Vienna and standing in front of my writing desk, I knew without a moment's hesitation where it was that, in my 'absent-mindedness', I had put the card with the address on it. In my unconscious hiding of the thing the same intention had been operative as in my curiously modified act of forgetting.

SCREEN MEMORIES

Intentionally left blank

SCREEN MEMORIES

In the course of my psycho-analytic treatment of cases of hysteria, obsessional neurosis, etc., I have often had to deal with fragmentary recollections which have remained in the patient's memory from the earliest years of his childhood. As I have shown elsewhere, great pathogenic importance must be attributed to the impressions of that time of life. But the subject of childhood memories is in any case bound to be of psychological interest, for they bring into striking relief a fundamental difference between the psychical functioning of children and of adults. No one calls in question the fact that the experiences of the earliest years of our childhood leave ineradicable traces in the depths of our minds. If, however, we seek in our *memories* to ascertain what were the impressions that were destined to influence us to the end of our lives, the outcome is either nothing at all or a relatively small number of isolated recollections which are often of dubious or enigmatic importance. It is only from the sixth or seventh year onwards - in many cases only after the tenth year - that our lives can be reproduced in memory as a connected chain of events. From that time on, however, there is also a direct relation between the psychical significance of an experience and its retention in the memory. Whatever seems important on account of its immediate or directly subsequent effects is recollected; whatever is judged to be inessential is forgotten. If I can remember an event a long time after its occurrence, I regard the fact of having retained it in my memory as evidence of its having made a deep impression on me at the time. I feel surprised at forgetting; and I feel even more surprised, perhaps, at remembering something apparently indifferent.

It is only in certain pathological mental conditions that the relation holding in normal adults between the psychical significance of an event and its retention in memory once more ceases to apply. For instance, a hysteric habitually shows amnesia for some or all of the experiences which led to the onset of his illness and which from that very fact have become important to him and, apart from that fact, may have been important on their own account. The analogy between pathological amnesia of this kind and the normal amnesia affecting our early years seems to me to give a valuable hint at the intimate connection that exists between the psychical content of neuroses and our infantile life.

We are so much accustomed to this lack of memory of the impressions of childhood that we are apt to overlook the problem underlying it and are inclined to explain it as a self-evident consequence of the rudimentary character of the mental activities of children. Actually, however, a normally developed child of three or four already exhibits an enormous amount of highly organized mental functioning in the comparisons and inferences which he makes and in the expression of his feelings; and there is no obvious reason why amnesia should overtake these psychical acts, which carry no less weight than those of a later age.

Before dealing with the psychological problems attaching to the earliest memories of childhood, it would of course be essential to make a collection of material by circularizing a fairly large number of normal adults and discovering what kind of recollections they are able to produce from these early years. A first step in this direction was taken in 1895 by V. and C. Henri, who sent round a paper of questions drawn up by them. The highly suggestive results of their questionnaire, which brought in replies from 123 persons, were published by the two authors in 1897. I have no intention at present of discussing the subject as a whole, and I shall therefore content myself with emphasizing the few points which will enable me to introduce the notion of what I have termed 'screen memories'.

The age to which the content of the earliest memories of childhood is usually referred back is the period between the ages of two and four. (This is the case with 88 persons in the series observed by the Henris.) There are some, however, whose memory reaches back further - even to the time before the completion of their first year; and, on the other hand, there are some whose earliest recollections go back only to their sixth, seventh, or even eighth year. There is nothing at the moment to show what else is related to these individual differences; is to be noticed, say the Henris, that a person whose earliest recollection goes back to a very tender age - to the first year of his life, perhaps - will also have at his disposal further detached memories from the following years, and that he will be able to reproduce his experiences as a continuous chain from an earlier point of time - from about his fifth year - than is possible for other people, whose first recollection dates from a later time. Thus not only the date of the appearance of the first recollection but the whole function of memory may, in the case of some people, be advanced or retarded.

Quite special interest attaches to the question of what is the usual *content* of these earliest memories of childhood. The psychology of adults would necessarily lead us to expect that those experiences would be selected as worth remembering which had aroused some powerful emotion or which, owing to their consequences, had been recognized as important soon after their occurrence. And some indeed of the observations collected by the Henris appear to fulfil this expectation. They report that the most frequent content of the first memories of childhood are on the one hand occasions of fear, shame, physical pain, etc., and on the other hand important events such as illnesses, deaths, fires, births of brothers and sisters, etc. We might therefore be inclined to assume that the principle governing the choice of memories is the same in the case of children as in that of adults. It is intelligible - though the fact deserves to be explicitly mentioned - that the memories retained from childhood should necessarily show evidence of the difference between what attracts the interest of a child and of an adult. This easily explains why, for instance, one woman reports that she remembers a number of accidents that occurred to her dolls when she was two years old but has no recollection of the serious and tragic events she might have observed at the same period.

Now, however, we are met by a fact that is diametrically opposed to our expectations and cannot fail to astonish us. We hear that there are some people whose earliest recollections of childhood are concerned with everyday and indifferent events which could not produce any emotional effect even in children, but which are recollected (*too* clearly, one is inclined to say) in every detail, while approximately contemporary events, even if, on the evidence of their parents, they moved them intensely at the time, have not been retained in their memory. Thus the Henris mention a professor of philology whose earliest memory, dating back to between the ages of three and four, showed him a table laid for a meal and on it a basin of ice. At the same period there occurred the death of his grandmother which, according to his parents, was a severe blow to the child. But the professor of philology, as he now is, has no recollection of this bereavement; all that he remembers of those days is the basin of ice. Another man reports that his earliest memory is an episode upon a walk in which he broke off a branch from a tree. He thinks he can still identify the spot where this happened. There were several other people present, and one of them helped him.

The Henris describe such cases as rare. In my experience, based for the most part, it is true, on neurotics, they are quite frequent. One of the subjects of the Henris' investigation made an attempt at explaining the occurrence of these mnemic images, whose innocence makes them so mysterious, and his explanation seems to me very much to the point. He thinks that in such cases the relevant scene may perhaps have been only *incompletely* retained in the memory, and that that may be why it seems so unenlightening: the parts that have been forgotten probably contained everything that made the experience noteworthy. I am able to confirm the truth of this view, though I should prefer to speak of these elements of the experience being *omitted* rather than forgotten. I have often succeeded, by means of psycho-analytic treatment, in uncovering the missing portions of a childhood experience and in thus proving that when the impression, of which no more than a torso was retained in the memory, had been restored to completeness, it did in fact agree with the presumption that it is the most important things that are recollected. This, however, provides no explanation of the remarkable choice which memory has made among the elements of the experience. We must first enquire why it should be that precisely what is important is suppressed and what is indifferent retained; and we shall not find an explanation of this until we have investigated the mechanism of these processes more deeply. We shall then form a notion that two psychical forces are concerned in bringing about memories of this sort. One of these forces takes the importance of the experience as a motive for seeking to remember it, while the other - a resistance - tries to prevent any such preference from being shown. These two opposing forces do not cancel each other out, nor does one of them (whether with or without loss to itself) overpower the other. Instead, a compromise is brought about, somewhat on the analogy of the resultant in a parallelogram of forces. And the compromise is this. What is recorded as a mnemic image is not the relevant experience itself - in this respect the resistance gets its way; what is recorded is another psychical element closely associated with the objectionable one - and in this respect the *first* principle shows its strength, the principle which endeavours to fix important impressions by establishing reproducible mnemic images. The result of the conflict is therefore that, instead of the mnemic image which would have been justified by the original event, another is produced which has been to some degree associatively *displaced* from the former one. And since the elements of the experience which aroused objection were precisely the important ones, the substituted memory will necessarily lack those important elements and will in consequence most probably strike us as trivial. It will seem incomprehensible to us because we are inclined to look for the reason for its retention in its own content, whereas in fact that retention is due to the relation holding between its own content and a different one which has been suppressed. There is a common saying among us about shams, that they are not made of gold themselves but have lain beside something that is made of gold. The same simile might well be applied to some of the experiences of childhood which have been retained in the memory.

There are numerous possible types of case in which one psychical content is substituted for another, and these come about in a variety of psychological constellations. One of the simplest of these cases is obviously that occurring in the childhood memories with which we are here concerned - the case, that is, where the essential elements of an experience are represented in memory by the inessential elements of the same experience. It is a case of displacement on to something associated by continuity; or, looking at the process as a whole, a case of repression accompanied by the substitution of something in the neighbourhood (whether in space or time). I have elsewhere¹ had occasion to describe a very similar instance of substitution which occurred in the analysis of a patient suffering from paranoia. The woman in question hallucinated voices, which used to repeat long passages from Otto Ludwig's novel *Die Heiterethei* to her. But the passages they chose were the most trifling and irrelevant in the book. The analysis showed, however, that there were other passages in the same work which had stirred up the most distressing thoughts in the patient. The distressing affect was a motive for putting up a defence against them, but the motives in favour of pursuing them further were not to be suppressed. The result was a compromise by which the innocent passages emerged in the patient's memory with pathological strength and clarity. The process which we here see at work - conflict, repression, substitution involving a compromise - returns in all psychoneurotic symptoms and gives us the key to understanding their formation. Thus it is not without importance if we are able to show the same process operating in the mental life of normal individuals, and the fact that what it influences in normal people is precisely their choice of childhood memories seems to afford one more indication of the intimate relations which have already been insisted upon between the mental life of children and the psychical material of the neuroses.

The processes of normal and pathological defence and the displacements in which they result are clearly of great importance. But to the best of my knowledge no study whatever has hitherto been made of them by psychologists; and it remains to be ascertained in what strata of psychical activity and under what conditions they come into operation. The reason for this neglect may well be that our mental life, so far as it is the object of our *conscious* internal perception, shows nothing of these processes, apart from instances which we classify as 'faulty reasoning' and some mental operations which aim at producing a comic effect. The assertion that a psychical intensity can be displaced from one presentation (which is then abandoned) on to another (which thenceforward plays the psychological part of the former one) is as bewildering to us as certain features of Greek mythology - as, for instance, when the gods are said to clothe someone with beauty as though it were with a veil, whereas we think only of a face transfigured by a change of expression.

¹ 'Further Remarks on the Neuro-Psychoses of Defence' (1896*b*).

Further investigation of these indifferent childhood memories has taught me that they can originate in other ways as well and that an unsuspected wealth of meaning lies concealed behind their apparent innocence. But on this point I shall not content myself with a mere assertion but shall give a detailed report of one particular instance which seems to me the most instructive out of a considerable number of similar ones. Its value is certainly increased by the fact that it relates to someone who is not at all or only very slightly neurotic.

The subject of this observation is a man of university education, aged thirty-eight. Though his own profession lies in a very different field, he has taken an interest in psychological questions ever since I was able to relieve him of a slight phobia by means of psycho-analysis. Last year he drew my attention to his childhood memories, which had already played some part in his analysis. After studying the investigation made by V. and C. Henri, he gave me the following summarized account of his own experience.

'I have at my disposal a fair number of early memories of childhood which I can date with great certainty. For at the age of three I left the small place where I was born and moved to a large town; and all these memories of mine relate to my birth place and therefore date from my second and third years. They are mostly short scenes, but they are very well preserved and furnished with every detail of sense-perception, in complete contrast to my memories of adult years, which are entirely lacking in the visual element. From my third year onwards my recollections grow scantier and less clear; there are gaps in them which must cover more than a year; and it is not, I believe, until my sixth or seventh year that the stream of my memories becomes continuous. My memories up to the time of my leaving my first place of residence fall into three groups. The first group consists of scenes which my parents have repeatedly since described to me. As regards these, I feel uncertain whether I have had the mnemonic image from the beginning or whether I only construed it after hearing one of these descriptions. I may remark, however, that there are also events of which I have no mnemonic image in spite of their having been frequently retailed by my parents. I attach more importance to the second group. It comprises scenes which have not (so far as I know) been described to me and some of which, indeed, could not have been described to me, as I have not met the other participants in them (my nurse and playmates) since their occurrence. I shall come to the third group presently. As regards the content of these scenes and their consequent claim to being recollected, I should like to say that I am not entirely at sea. I cannot maintain, indeed, that what I have retained are memories of the most important events of the period, or what I should to-day judge to be the most important. I have no knowledge of the birth of a sister, who is two and a half years younger than I am; my departure, my first sight of the railway and the long carriage-drive before it - none of these has left a trace in my memory. On the other hand, I can remember two small occurrences during the railway-journey; these, as you will recollect, came up in the analysis of my phobia. But what should have made most impression on me was an injury to my face which caused a considerable loss of blood and for which I had to have some stitches put in by a surgeon. I can still feel the scar resulting from this accident, but I know of no recollection which points to it, either directly or indirectly. It is true that I may perhaps have been under two years old at the time.

'It follows from this that I feel no surprise at the pictures and scenes of these first two groups. No doubt they are displaced memories from which the essential element has for the most part been omitted. But in a few of them it is at least hinted at, and in others it is easy for me to complete them by following certain pointers. By doing so I can establish a sound connection between the separate fragments of memories and arrive at a clear understanding of what the childish interest was that recommended these particular occurrences to my memory. This does not apply, however, to the content of the third group, which I have not so far discussed. There I am met by material - one rather long scene and several smaller pictures - with which I can make no headway at all. The scene appears to me fairly indifferent and I cannot understand why it should have become fixed in my memory. Let me describe it to you. I see a rectangular, rather steeply sloping piece of meadow-land, green and thickly grown; in the green there are a great number of yellow flowers - evidently common dandelions. At the top end of the meadow there is a cottage and in front of the cottage door two women are standing chatting busily, a peasant-woman with a handkerchief on her head and a children's nurse. Three children are playing in the grass. One of them is myself (between the age of two and three); the two others are my boy cousin, who is a year older than me, and his sister, who is almost exactly the same age as I am. We are picking the yellow flowers and each of us is holding a bunch of flowers we have already picked. The little girl has the best bunch; and, as though by mutual agreement, we - the two boys - fall on her and snatch away her flowers. She runs up the meadow in tears and as a consolation the peasant-woman gives her a big piece of black bread. Hardly have we seen this than we throw the flowers away, hurry to the cottage and ask to be given some bread too. And we are in fact given some; the peasant-woman cuts the loaf with a long knife. In my memory the bread tastes quite delicious - and at that point the scene breaks off.

'Now what is there in this occurrence to justify the expenditure of memory which it has occasioned me? I have racked my brains in vain over it. Does the emphasis lie on our disagreeable behaviour to the little girl? Did the yellow colour of the dandelions- a flower which I am, of course, far from admiring to-day - so greatly please me? Or, as a result of my careering round the grass, did the bread taste so much nicer than usual that it made an unforgettable impression on me? Nor can I find any connection between this scene and the interest which (as I was able to discover without any difficulty) bound together the other scenes from my childhood. Altogether, there seems to me something not quite right about this scene. The yellow of the flowers is a disproportionately prominent element in the situation as a whole, and the nice taste of the bread seems to me exaggerated in an almost hallucinatory fashion. I cannot help being reminded of some pictures that I once saw in a burlesque exhibition. Certain portions of these pictures, and of course the most inappropriate ones, instead of being painted, were built up in three dimensions - for instance, the ladies' bustles. Well, can you point out any way of finding an explanation or interpretation of this redundant memory of my childhood?'

I thought it advisable to ask him since when he had been occupied with this recollection: whether he was of opinion that it had recurred to his memory periodically since his childhood, or whether it had perhaps emerged at some later time on some occasion that could be recalled. This question was all that it was necessary for me to contribute to the solution of the problem; the rest was found by my collaborator himself, who was no novice at jobs of this kind.

'I have not yet considered that point,' he replied. 'Now that you have raised the question, it seems to me almost a certainty that this childhood memory never occurred to me at all in my earlier years. But I can also recall the occasion which led to my recovering this and many other recollections of my earliest childhood. When I was seventeen and at my secondary school, I returned for the first time to my birthplace for the holidays, to stay with a family who had been our friends ever since that remote date. I know quite well what a wealth of impressions overwhelmed me at that time. But I see now that I shall have to tell you a whole big piece of my history: it belongs here, and you have brought it upon yourself by your question. So listen. I was the child of people who were originally well-to-do and who, I fancy, lived comfortably enough in that little corner of the provinces. When I was about three, the branch of industry in which my father was concerned met with a catastrophe. He lost all his means and we were forced to leave the place and move to a large town. Long and difficult years followed, of which, as it seems to me, nothing was worth remembering. I never felt really comfortable in the town. I believe now that I was never free from a longing for the beautiful woods near our home, in which (as one of my memories from those days tells me) I used to run off from my father, almost before I had learnt to walk. Those holidays, when I was seventeen, were my first holidays in the country, and, as I have said, I stayed with a family with whom we were friends and who had risen greatly in the world since our move. I could compare the comfort reigning there with our own style of living at home in the town. But it is no use evading the subject any longer: I must admit that there was something else that excited me powerfully. I was seventeen, and in the family where I was staying there was a daughter of fifteen, with whom I immediately fell in love. It was my first calf-love and sufficiently intense, but I kept it completely secret. After a few days the girl went off to her school (from which she too was home for the holidays) and it was this separation after such a short acquaintance that brought my longings to a really high pitch. I passed many hours in solitary walks through the lovely woods that I had found once more and spent my time building castles in the air. These, strangely enough, were not concerned with the future but sought to improve the past. If only the smash had not occurred! If only I had stopped at home and grown up in the country and grown as strong as the young men in the house, the brothers of my love! And then if only I had followed my father's profession and if I had finally married her - for I should have known her intimately all those years! I had not the slightest doubt, of course, that in the circumstances created by my imagination I should have loved her just as passionately as I really seemed to then. A strange thing. For when I see her now from time to time - she happens to have married someone here - she is quite exceptionally indifferent to me. Yet I can remember quite well for what a long time afterwards I was affected by the yellow colour of the dress she was wearing when we first met, whenever I saw the same colour anywhere else.'

That sounds very much like your parenthetical remark to the effect that you are no longer fond of the common dandelion. Do you not suspect that there may be a connection between the yellow of the girl's dress and the ultra-clear yellow of the flowers in your childhood scene?

'Possibly. But it was not the same yellow. The dress was more of a yellowish brown, more like the colour of wallflowers. However, I can at least let you have an intermediate idea which may serve your purpose. At a later date, while I was in the Alps, I saw how certain flowers which have light colouring in the lowlands take on darker shades at high altitudes. Unless I am greatly mistaken, there is frequently to be found in mountainous regions a flower which is very similar to the dandelion but which is dark yellow and would exactly agree in colour with the dress of the girl I was so fond of. But I have not finished yet. I now come to a second occasion which stirred up in me the impressions of my childhood and which dates from a time not far distant from the first. I was seventeen when I revisited my birthplace. Three years later during my holidays I visited my uncle and met once again the children who had been my first playmates, the same two cousins, the boy a year older than I am and the girl of the same age as myself, who appear in the childhood scene with the dandelions. This family had left my birthplace at the same time as we did and had become prosperous in a far-distant city.'

And did you once more fall in love - with your cousin this time - and indulge in a new set of phantasies?

'No, this time things turned out differently. By then I was at the University and I was a slave to my books. I had nothing left over for my cousin. So far as I know I had no similar phantasies on that occasion. But I believe that my father and my uncle had concocted a plan by which I was to exchange the abstruse subject of my studies for one of more practical value, settle down, after my studies were completed, in the place where my uncle lived, and marry my cousin. No doubt when they saw how absorbed I was in my own intentions the plan was dropped; but I fancy I must certainly have been aware of its existence. It was not until later, when I was a newly-fledged man of science and hard pressed by the exigencies of life and when I had to wait so long before finding a post here, that I must sometimes have reflected that my father had meant well in planning this marriage for me, to make good the loss in which the original catastrophe had involved my whole existence.'

Then I am inclined to believe that the childhood scene we are considering emerged at this time, when you were struggling for your daily bread - provided, that is, that you can confirm my idea that it was during this same period that you first made the acquaintance of the Alps.

'Yes, that is so: mountaineering was the one enjoyment that I allowed myself at that time. But I still cannot grasp your point.'

I am coming to it at once. The element on which you put most stress in your childhood scene was the fact of the country-made bread tasting so delicious. It seems clear that this idea, which amounted almost to a hallucination, corresponded to your phantasy of the comfortable life you would have led if you had stayed at home and married this girl - or, in symbolic language, of how sweet the bread would have tasted for which you had to struggle so hard in your later years. The yellow of the flowers, too, points to the same girl. But there are also elements in the childhood scene which can only be related to the *second* phantasy - of being married to your cousin. Throwing away the flowers in exchange for bread strikes me as not a bad disguise for the scheme your father had for you: you were to give up your unpractical ideals and take on a 'bread-and-butter' occupation, were you not?

'It seems then that I amalgamated the two sets of phantasies of how my life could have been more comfortable -the "yellow" and the "country-made bread" from the one and the throwing away of the flowers and the actual people concerned from the other.'

Yes. You projected the two phantasies on to one another and made a childhood memory of them. The element about the Alpine flowers is as it were a stamp giving the date of manufacture. I can assure you that people often construct such things unconsciously - almost like works of fiction.

'But if that is so, there was *no* childhood memory, but only a phantasy put back into childhood. A feeling tells me, though, that the scene is genuine. How does that fit in?'

There is in general no guarantee of the data produced by our memory. But I am ready to agree with you that the scene is genuine. If so, you selected it from innumerable others of a similar or another kind because, on account of its content (which in itself was indifferent) it was well adapted to represent the two phantasies, which were important enough to you. A recollection of this kind, whose value lies in the fact that it represents in the memory impressions and thoughts of a later date whose content is connected with its own by symbolic or similar links, may appropriately be called a '*screen memory*'. In any case you will cease to feel any surprise that this scene should so often recur to your mind. It can no longer be regarded as an innocent one since, as we have discovered, it is calculated to illustrate the most momentous turning-points in your life, the influence of the two most powerful motive forces - hunger and love.

‘Yes, it represented hunger well enough. But what about love?’

In the yellow of the flowers, I mean. But I cannot deny that in this childhood scene of yours love is represented far less prominently than I should have expected from my previous experience.

‘No. You are mistaken. The essence of it is its representation of love. Now I understand for the first time. Think for a moment! Taking flowers away from a girl means to deflower her. What a contrast between the boldness of this phantasy and my bashfulness on the first occasion and my indifference on the second.’

I can assure you that youthful bashfulness habitually has as its complement bold phantasies of that sort.

‘But in that case the phantasy that has transformed itself into these childhood memories would not be a conscious one that I can remember, but an unconscious one?’

Unconscious thoughts which are a prolongation of conscious ones. You think to yourself ‘If I had married so-and-so’, and behind the thought there is an impulse to form a picture of what the ‘being married’ really is.

‘I can go on with it now myself. The most seductive part of the whole subject for a young scapegrace is the picture of the marriage night. (What does he care about what comes afterwards?) But that picture cannot venture out into the light of day: the dominating mood of diffidence and of respect towards the girl keeps it suppressed. So it remains unconscious-’

And slips away into a childhood memory. You are quite right. It is precisely the coarsely sensual element in the phantasy which explains why it does not develop into a *conscious* phantasy but must be content to find its way allusively and under a flowery disguise into a childhood scene.

'But why precisely, into a *childhood* scene, I should like to know?'

For the sake of its innocence, perhaps. Can you imagine a greater contrast to these designs for gross sexual aggression than childish pranks? However, there are more general grounds that have a decisive influence in bringing about the slipping away of repressed thoughts and wishes into childhood memories: for you will find the same thing invariably happening in hysterical patients. It seems, moreover, as though the recollection of the remote past is in itself facilitated by some pleasurable motive: *forsan et haec olim meminisse juvabit*.¹

'If that is so, I have lost all faith in the genuineness of the dandelion scene. This is how I look at it: On the two occasions in question, and with the support of very comprehensible realistic motives, the thought occurred to me: "If you had married this or that girl, your life would have become much pleasanter." The sensual current in my mind took hold of the thought which is contained in the protasis and repeated it in images of a kind capable of giving that same sensual current satisfaction. This second version of the thought remained unconscious on account of its incompatibility with the dominant sexual disposition; but this very fact of its remaining unconscious enabled it to persist in my mind long after changes in the real situation had quite got rid of the conscious version. In accordance, as you say, with a general law, the clause that had remained unconscious sought to transform itself into a childhood scene which, on account of its innocence, would be able to become conscious. With this end in view it had to undergo a fresh transformation, or rather two fresh transformations. One of these removed the objectionable element from the protasis by expressing it figuratively; the second forced the apodosis into a shape capable of visual representation - using for the purpose the intermediary ideas of "bread" and "bread-and-butter occupations". I see that by producing a phantasy like this I was providing, as it were, a fulfilment of the two suppressed wishes for deflowering a girl and for material comfort. But now that I have given such a complete account of the motives that led to my producing the dandelion phantasy, I cannot help concluding that what I am dealing with is something that never happened at all but has been unjustifiably smuggled in among my childhood memories.'

¹ ['Some day, perhaps, it will be a joy to remember even these things.']

I see that I must take up the defence of its genuineness. You are going too far. You have accepted my assertion that every suppressed phantasy of this kind tends to slip away into a childhood scene. But suppose now that this cannot occur unless there is a memory-trace the content of which offers the phantasy a point of contact - comes, as it were, half way to meet it. Once a point of contact of this kind has been found - in the present instance it was the deflowering, the taking away of the flowers - the remaining content of the phantasy is remodelled with the help of every legitimate intermediate idea - take the bread as an example - till it can find further points of contact with the content of the childhood scene. It is very possible that in the course of this process the childhood scene itself also undergoes changes; I regard it as certain that falsifications of memory may be brought about in this way too. In your case the childhood scene seems only to have had some of its lines engraved more deeply: think of the over-emphasis on the yellow and the exaggerated niceness of the bread. But the raw material was utilisable. If that had not been so, it would not have been possible for this particular memory, rather than any others, to make its way forward into consciousness. No such scene would have occurred to you as a childhood memory, or perhaps some other one would have - for you know how easily our ingenuity can build connecting bridges from any one point to any other. And apart from your own subjective feeling which I am not inclined to under-estimate, there is another thing that speaks in favour of the genuineness of your dandelion memory. It contains elements which have not been solved by what you have told me and which do not in fact fit in with the sense required by the phantasy. For instance, your boy cousin helping you to rob the little girl of her flowers - can you make any sense of the idea of being helped in deflowering someone? or of the peasant woman and the nurse in front of the cottage?

'Not that I can see.'

So the phantasy does not coincide completely with the childhood scene. It is only based on it at certain points. That argues in favour of the childhood memory being genuine.

'Do you think an interpretation like this of an apparently innocent childhood memory is often applicable?'

Very often, in my experience. Shall we amuse ourselves by seeing whether the two examples given by the Henris can be interpreted as screen memories concealing subsequent experiences and wishes? I mean the memory of a table laid for a meal with a basin of ice on it, which was supposed to have some connection with the death of the subject's grandmother, and the other memory, of a child breaking off a branch from a tree while he was on a walk and of his being helped to do it by someone.

He reflected for a little and then answered: 'I can make nothing of the first one. It is most probably a case of displacement at work; but the intermediate steps are beyond guessing. As for the second case, I should be prepared to give an interpretation, if only the person concerned had not been a Frenchman.'

I cannot follow you there. What difference would that make?

'A great deal of difference, since what provides the intermediate step between a screen memory and what it conceals is likely to be a verbal expression. In German "to pull one out" is a very common vulgar term for masturbation. The scene would then be putting back into early childhood a seduction to masturbation - someone was helping him to do it - which in fact occurred at a later period. But even so, it does not fit, for in the childhood scene there were a number of other people present.'

Whereas his seduction to masturbate must have occurred in solitude and secrecy. It is just that contrast that inclines me to accept your view: it serves once again to make the scene innocent. Do you know what it means when in a dream we see 'a lot of strangers', as happens so often in dreams of nakedness in which we feel so terribly embarrassed? Nothing more nor less than secrecy, which there again is expressed by its opposite. However, our interpretation remains a jest, since we have no idea whether a Frenchman would recognize an allusion to masturbation in the words *casser une branche d'un arbre* or in some suitably emended phrase.

This analysis, which I have reproduced as accurately as possible, will, I hope, have to some extent clarified the concept of a 'screen memory' as one which owes its value as a memory not to its own content but to the relation existing between that content and some other, that has been suppressed. Different classes of screen memories can be distinguished according to the nature of that relation. We have found examples of two of these classes among what are described as the earliest memories of childhood - that is, if we include under the heading of screen memories the incomplete childhood scenes which are innocent by very reason of their incompleteness. It is to be anticipated that screen memories will also be formed from residues of memories relating to later life as well. Anyone who bears in mind their distinctive feature - namely that they are extremely well remembered but that their content is completely indifferent - will easily recall a number of examples of the sort from his own memory. Some of these screen memories dealing with events later in life owe their importance to a connection with experiences in early youth which have remained suppressed. The connection, that is, is the reverse of the one in the case which I have analysed, where a childhood memory was accounted for by later experiences. A screen memory may be described as 'retrogressive' or as having 'pushed forward' according as the one chronological relation or the other holds between the screen and the thing screened-off. From another point of view, we can distinguish positive screen memories from negative ones (or refractory memories) whose content stands in a contrary relation to the suppressed material. The whole subject deserves a more thorough examination; but I must content myself with pointing out what complicated processes - processes, incidentally, which are altogether analogous to the formation of hysterical symptoms - are involved in the building up of our store of memories.

Our earliest childhood memories will always be a subject of special interest because the problem mentioned at the beginning of this paper (of how it comes about that the impressions which are of most significance for our whole future usually leave no mnemonic images behind) leads us to reflect upon the origin of conscious memories in general. We shall no doubt be inclined at first to separate off the screen memories which are the subject of this study as heterogeneous elements among the residues of childhood recollections. As regards the remaining images, we shall probably adopt the simple view that they arise simultaneously with an experience as an immediate consequence of the impression it makes and that thereafter they recur from time to time in accordance with the familiar laws of reproduction. Closer observation, however, reveals certain features which do not tally with this view. Above all, there is the following point. In the majority of significant and in other respects unimpeachable childhood scenes the subject sees himself in the recollection as a child, with the knowledge that this child is himself; he sees this child, however, as an observer from outside the scene would see him. The Henris duly draw attention to the fact that many of those taking part in their investigation expressly emphasized this peculiarity of childhood scenes. Now it is evident that such a picture cannot be an exact repetition of the impression that was originally received. For the subject was then in the middle of the situation and was attending not to himself but to the external world.

Whenever in a memory the subject himself appears in this way as an object among other objects this contrast between the acting and the recollecting ego may be taken as evidence that the original impression has been worked over. It looks as though a memory-trace from childhood had here been translated back into a plastic and visual form at a later date - the date of the memory's arousal. But no reproduction of the original impression has ever entered the subject's consciousness.

There is another fact that affords even more convincing evidence in favour of this second view. Out of a number of childhood memories of significant experiences, all of them of similar distinctness and clarity, there will be some scenes which, when they are tested (for instance by the recollections of adults), turn out to have been falsified. Not that they are complete inventions; they are false in the sense that they have shifted an event to a place where it did not occur - this is the case in one of the instances quoted by the Henris - or that they have merged two people into one or substituted one for the other, or the scenes as a whole give signs of being combinations of two separate experiences. Simple inaccuracy of recollection does not play any considerable part here, in view of the high degree of sensory intensity possessed by the images and the efficiency of the function of memory in the young; close investigation shows rather that these falsifications of memory are tendentious - that is, that they serve the purposes of the repression and replacement of objectionable or disagreeable impressions. It follows, therefore, that these falsified memories too, must have originated at a period of life when it has become possible for conflicts of this kind and impulses towards repression to have made a place for themselves in mental life - far later, therefore, than the period to which their content belongs. But in these cases too the falsified memory is the first that we become aware of: the raw material of memory-traces out of which it was forged remains unknown to us in its original form.

The recognition of this fact must diminish the distinction we have drawn between screen memories and other memories derived from our childhood. It may indeed be questioned whether we have any memories at all *from* our childhood: memories *relating to* our childhood may be all that we possess. Our childhood memories show us our earliest years not as they were but as they appeared at the later periods when the memories were aroused. In these periods of arousal, the childhood memories did not, as people are accustomed to say, *emerge*; they were *formed* at that time. And a number of motives, with no concern for historical accuracy, had a part in forming them, as well as in the selection of the memories themselves.

AUTOBIOGRAPHICAL NOTE
(1901)

Intentionally left blank

AUTOBIOGRAPHICAL NOTE

FREUD, SIGM., Vienna. Born May 6, 1856, at Freiberg in Moravia. Studied in Vienna. Pupil of Brücke, the physiologist. Promotion, 1881. Pupil of Charcot in Paris 1885-6. Habilitation, 1885. Has worked as physician and Dozent at Vienna University since 1886. Proposed as Professor Extraordinarius, 1897. Earlier Freud produced writings on histology and cerebral anatomy and, subsequently, clinical works on neuropathology; translated writings by Charcot and Bernheim. In 1884 'Über Coca', a paper which introduced cocaine into medicine. In 1891 *Zur Auffassung der Aphasien*. In 1891 and 1893 monographs on the cerebral palsies of children, which culminated in 1897 in the volume on the subject in Nothnagel's *Handbuch*. In 1895 *Studien über Hysterie* (with Dr. J. Breuer). Since then Freud has turned to the study of the psychoneuroses and especially hysteria, and in a series of shorter works he has stressed the aetiological significance of sexual life for the neuroses. He has also developed a new psychotherapy of hysteria, on which only extremely little has been published. A book, *Die Traumdeutung*, is in the press.

THE INTERPRETATION OF DREAMS
(1900)

Flectere si nequero superos, Acheronta movebo

Preface to the First Edition

I have attempted in this volume to give an account of the interpretation of dreams; and in doing so I have not, I believe, trespassed beyond the sphere of interest covered by neuro-pathology. For psychological investigation shows that the dream is the first member of a class of abnormal psychological phenomena of which further members, such as hysterical phobias, obsessions and delusions, are bound for practical reasons to be a matter of concern to physicians. As will be seen in the sequel, dreams can make no such claim to practical importance; but their theoretical value as a paradigm is on the other hand proportionately greater. Anyone who has failed to explain the origin of dream-images can scarcely hope to understand phobias, obsessions or delusions or to bring a therapeutic influence to bear on them.

But the same correlation that is responsible for the importance of the subject must also bear the blame for the deficiencies of the present work. The broken threads which so frequently interrupt my presentation are nothing less than the many points of contact between the problem of the formation of dreams and the more comprehensive problems of psycho pathology. These cannot be treated here, but, if time and strength allow and further material comes to hand, will form the subject of later communications.

The difficulties of presentation have been further increased by the peculiarities of the material which I have had to use to illustrate the interpreting of dreams. It will become plain in the course of the work itself why it is that none of the dreams already reported in the literature of the subject or collected from unknown sources could be of any use for my purposes. The only dreams open to my choice were my own and those of my patients undergoing psycho-analytic treatment. But I was precluded from using the latter material by the fact that in its case the dream-processes were subject to an undesirable complication owing to the added presence of neurotic features. But if I was to report my own dreams, it inevitably followed that I should have to reveal to the public gaze more of the intimacies of my mental life than I liked, or than is normally necessary for any writer who is a man of science and not a poet. Such was the painful but unavoidable necessity; and I have submitted to it rather than totally abandon the possibility of giving the evidence for my psychological findings. Naturally, however, I have been unable to resist the temptation of taking the edge off some of my indiscretions by omissions and substitutions. But whenever this has happened, the value of my instance has been very definitely diminished. I can only express a hope that readers of this book will put themselves in my difficult situation and treat me with indulgence, and further, that anyone who finds any sort of reference to himself in my dreams may be willing to grant me the right of freedom of thought - in my dream-life, if nowhere else.

Preface to the Second Edition

If within ten years of the publication of this book (which is very far from being an easy one to read) a second edition is called for, this is not due to the interest taken in it by the professional circles to whom my original preface was addressed. My psychiatric colleagues seem to have taken no trouble to overcome the initial bewilderment created by my new approach to dreams. The professional philosophers have become accustomed to polishing off the problems of dream-life (which they treat as a mere appendix to conscious states) in a few sentences - and usually in the same ones; and they have evidently failed to notice that we have something here from which a number of inferences can be drawn that are bound to transform our psychological theories. The attitude adopted by reviewers in the scientific periodicals could only lead one to suppose that my work was doomed to be sunk into complete silence; while the small group of gallant supporters, who practise medical psycho-analysis under my guidance and who follow my example in interpreting dreams and make use of their interpretations in treating neurotics, would never have exhausted the first edition of the book. Thus it is that I feel indebted to a wider circle of educated and curious-minded readers, whose interest has led me to take up once more after nine years this difficult, but in many respects fundamental, work.

I am glad to say that I have found little to change in it. Here and there I have inserted some new material, added some fresh points of detail derived from my increased experience, and at some few points recast my statements. But the essence of what I have written about dreams and their interpretation, as well as about the psychological theorems to be deduced from them - all this remains unaltered: subjectively at all events, it has stood the test of time. Anyone who is acquainted with my other writings (on the aetiology and mechanism of the psycho-neuroses) will know that I have never put forward inconclusive opinions as though they were established facts, and that I have always sought to modify my statements so that they may keep in step with my advancing knowledge. In the sphere of dream-life I have been able to leave my original assertions unchanged. During the long years in which I have been working at the problems of the neuroses I have often been in doubt and some times been shaken in my convictions. At such times it has always been the *Interpretation of Dreams* that has given me back my certainty. It is thus a sure instinct which has led my many scientific opponents to refuse to follow me more especially in my researches upon dreams.

An equal durability and power to withstand any far-reaching alterations during the process of revision has been shown by the *material* of the book, consisting as it does of dreams of my own which have for the most part been overtaken or made valueless by the march of events and by which I illustrated the rules of dream-interpretation. For this book has a further subjective significance for me personally - a significance which I only grasped after I had completed it. It was, I found, a portion of my own self-analysis, my reaction to my father's death - that is to say, to the most important event, the most poignant loss, of a man's life. Having discovered that this was so, I felt unable to obliterate the traces of the experience. To my readers, however, it will be a matter of indifference upon what particular material they learn to appreciate the importance of dreams and how to interpret them.

Wherever I have found it impossible to incorporate some essential addition into the original context, I have indicated its more recent date by enclosing it in square brackets.¹

BERCHTESGADEN, *Summer* 1908

¹ [Footnote added 1914.] In later editions these were omitted.

Preface to the Third Edition

Nine years elapsed between the first and second editions of this book, but after scarcely more than a single year a third edition has become necessary. This new turn of events may please me; but just as formerly I was unwilling to regard the neglect of my book by readers as evidence of its worthlessness, so I cannot claim that the interest which is now being taken in it is a proof of its excellence.

Even the *Interpretation of Dreams* has not been left untouched by the advance of scientific knowledge. When I wrote it in 1899, my theory of sexuality was not yet in existence and the analysis of the more complicated forms of psycho-neurosis was only just beginning. It was my hope that dream-interpretation would help to make possible the psychological analysis of the neuroses; since then a deeper understanding of neuroses has reacted in turn upon our view of dreams. The theory of dream-interpretation has itself developed further in a direction on which insufficient stress had been laid in the first edition of this book. My own experience, as well as the works of Wilhelm Stekel and others, have since taught me to form a truer estimate of the extent and importance of symbolism in dreams (or rather in unconscious thinking). Thus in the course of these years much has accumulated which demands attention. I have endeavoured to take these innovations into account by making numerous interpolations in the text and by additional footnotes. If these additions threaten at times to burst the whole framework of the book or if I have not everywhere succeeded in bringing the original text up to the level of our present knowledge, I must ask the reader's indulgence for these deficiencies: they are the results and signs of the present increasingly rapid development of our science. I may even venture to prophesy in what other directions later editions of this book - if any should be needed - will differ from the present one. They will have on the one hand to afford a closer contact with the copious material presented in imaginative writing, in myths, in linguistic usage and in folklore; while on the other hand they will have to deal in greater detail than has here been possible with the relations of dreams to neuroses and mental diseases.

Herr Otto Rank has given me valuable assistance in selecting the additional matter and has been entirely responsible for correcting the proofs. I owe my thanks to him and to many others for their contributions and corrections.

VIENNA, *Spring* 1911

Preface to the Fourth Edition

Last year (1913) Dr. A. A. Brill of New York produced an English translation of this book (*The Interpretation of Dreams*, G. Allen & Co., London).

On this occasion Dr. Otto Rank has not only corrected the proofs but has also contributed two self-contained chapters to the text - the appendices to Chapter VI.

VIENNA, *June* 1914

Preface to the Fifth Edition

Interest in the *Interpretation of Dreams* has not flagged even during the World War, and while it is still in progress a new edition has become necessary. It has not been possible, however, to notice fully publications since 1914; neither Dr. Rank nor I have any knowledge of foreign works since that date.

A Hungarian translation, prepared by Dr. Hollós and Dr. Ferenczi, is on the point of appearing. In 1916-17 my *Introductory Lectures on Psycho-Analysis* were published in Vienna by Hugo Heller. The central section of these, comprising eleven lectures, is devoted to an account of dreams which aims at being more elementary and at being in closer contact with the theory of the neuroses than the present work. On the whole it is in the nature of an epitome of the *Interpretation of Dreams*, though at certain points it enters into greater detail.

I have not been able to bring myself to embark upon any fundamental revision of this book, which might bring it up to the level of our present psycho-analytic views but would on the other hand destroy its historic character. I think, however, that after an existence of nearly twenty years it has accomplished its task.

BUDAPEST-STEINBRUCH, *July* 1918

Preface to the Sixth Edition

Owing to the difficulties in which the book trade is placed at present, this new edition has long been in demand, and the preceding edition has, for the first time, been reprinted without any alterations. Only the bibliography at the end of the volume has been completed and brought up to date by Dr. Otto Rank.

Thus my assumption that after an existence of nearly twenty years this book had accomplished its task has not been confirmed. On the contrary, I might say that it has a new task to perform. If its earlier function was to offer some information on the nature of dreams, now it has the no less important duty of dealing with the obstinate misunderstandings to which that information is subject.

VIENNA, *April* 1921

Preface to the Eighth Edition

During the interval between the publication of the last (seventh) edition of this book in 1922 and the present one, my *Gesammelte Schriften* have been issued in Vienna by the Internationaler Psychoanalytischer Verlag. The second volume of that collection consists of an exact reprint of the first edition of the *Interpretation of Dreams*, while the third volume contains all the additions that have since been made to it. The translations of the book which have appeared during the same interval are based upon the usual, single-volume, form of the work: a French one by I. Meyerson published under the title of *La science des rêves* in the 'Bibliothèque de Philosophie Contemporaine' in 1926; a Swedish one by John Landquist, *Drömtydning* (1927); and a Spanish one by Luis López Ballesteros y de Torres, which occupies Volumes VI and VII of the *Obras Completas*. The Hungarian translation, which I thought was on the point of completion as long ago as in 1918, has even now not appeared.

In the present revised edition of the work I have again treated it essentially as an historic document and I have only made such alterations in it as were suggested by the clarification and deepening of my own opinions. In accordance with this, I have finally given up the idea of including a list of works on the problems of dreams published since the book's first appearance, and that section has now been dropped. The two essays which Otto Rank contributed to earlier editions, on 'Dreams and Creative Writing' and 'Dreams and Myths', have also been omitted.

VIENNA, *December* 1929

Preface to the Third (Revised) English Edition

In 1909 G. Stanley Hall invited me to Clark University, in Worcester, to give the first lectures on psycho-analysis. In the same year Dr. Brill published the first of his translations of my writings, which were soon followed by further ones. If psycho-analysis now plays a role in American intellectual life, or if it does so in the future, a large part of this result will have to be attributed to this and other activities of Dr. Brill's.

His first translation of *The Interpretation of Dreams* appeared in 1913. Since then much has taken place in the world, and much has been changed in our views about the neuroses. This book, with the new contribution to psychology which surprised the world when it was published (1900), remains essentially unaltered. It contains, even according to my present-day judgement, the most valuable of all the discoveries it has been my good fortune to make. Insight such as this falls to one's lot but once in a lifetime.

VIENNA, *March* 15, 1931

CHAPTER I

THE SCIENTIFIC LITERATURE DEALING WITH THE PROBLEMS OF DREAMS

In the pages that follow I shall bring forward proof that there is a psychological technique which makes it possible to interpret dreams, and that, if that procedure is employed, every dream reveals itself as a psychical structure which has a meaning and which can be inserted at an assignable point in the mental activities of waking life. I shall further endeavour to elucidate the processes to which the strangeness and obscurity of dreams are due and to deduce from those processes the nature of the psychical forces by whose concurrent or mutually opposing action dreams are generated. Having gone thus far, my description will break off, for it will have reached a point at which the problem of dreams merges into more comprehensive problems, the solution of which must be approached upon the basis of material of another kind.

I shall give by way of preface a review of the work done by earlier writers on the subject as well as of the present position of the problems of dreams in the world of science, since in the course of my discussion I shall not often have occasion to revert to those topics. For, in spite of many thousands of years of effort, the scientific understanding of dreams has made very little advance - a fact so generally admitted in the literature that it seems unnecessary to quote instances in support of it. In these writings, of which a list appears at the end of my work, many stimulating observations are to be found and a quantity of interesting material bearing upon our theme, but little or nothing that touches upon the essential nature of dreams or that offers a final solution of any of their enigmas. And still less, of course, has passed into the knowledge of educated laymen.

It may be asked what view was taken of dreams in prehistoric times by primitive races of men and what effect dreams may have had upon the formation of their conceptions of the world and of the soul; and this is a subject of such great interest that it is only with much reluctance that I refrain from dealing with it in this connection. I must refer my readers to the standard works of Sir John Lubbock, Herbert Spencer, E. B. Tylor and others, and I will only add that we shall not be able to appreciate the wide range of these problems and speculations until we have dealt with the task that lies before us here - the interpretation of dreams.

The prehistoric view of dreams is no doubt echoed in the attitude adopted towards dreams by the peoples of classical antiquity.¹ They took it as axiomatic that dreams were connected with the world of superhuman beings in whom they believed and that they were revelations from gods and daemons. There could be no question, moreover, that for the dreamer dreams had an important purpose, which was as a rule to foretell the future. The extraordinary variety in the content of dreams and in the impression they produced made it difficult, however, to have any uniform view of them and made it necessary to classify dreams into numerous groups and subdivisions according to their importance and trustworthiness. The position adopted towards dreams by individual philosophers in antiquity was naturally dependent to some extent upon their attitude towards divination in general.

In the two works of Aristotle which deal with dreams, they have already become a subject for psychological study. We are told that dreams are not sent by the gods and are not of a divine character, but that they are 'daemonic', since nature is 'daemonic' and not divine. Dreams, that is, do not arise from supernatural manifestations but follow the laws of the human spirit, though the latter, it is true, is akin to the divine. Dreams are defined as the mental activity of the sleeper in so far as he is asleep.

¹ What follows is based on Büchsenenschütz's scholarly study (1868).

Aristotle was aware of some of the characteristics of dream life. He knew, for instance, that dreams give a magnified construction to small stimuli arising during sleep. 'Men think that they are walking through fire and are tremendously hot, when there is only a slight heating about certain parts.' And from this circumstance he draws the conclusion that dreams may very well betray to a physician the first signs of some bodily change which has not been observed in waking.¹

Before the time of Aristotle, as we know, the ancients regarded dreams not as a product of the dreaming mind but as something introduced by a divine agency; and already the two opposing currents, which we shall find influencing opinions of dream-life at every period of history, were making themselves felt. The distinction was drawn between truthful and valuable dreams, sent to the sleeper to warn him or foretell the future, and vain, deceitful and worthless dreams, whose purpose it was to mislead or destroy him.

Gruppe (1906, 2, 930) quotes a classification of dreams on these lines made by Macrobius and Artemidorus: 'Dreams were divided into two classes. One class was supposed to be influenced by the present or past, but to have no future significance. It included the *ἐνύπνια* or insomnia, which gave a direct representation of a given idea or of its opposite - e.g. of hunger or of its satiation -, and the *φαντάσματα*, which lent a fantastic extension to the given idea - e.g. the nightmare or *ephialtes*. The other class, on the contrary, was supposed to determine the future. It included (1) direct prophecies received in a dream (the *χρηματισμός* or *oraculum*), (2) previsions of some future event (the *όραμα* or *visio*) and (3) symbolic dreams, which needed interpretation (the *όνειρος* or *somnium*). This theory persisted for many centuries.'

¹ The Greek physician Hippocrates deals with the relation of dreams to illnesses in one of the chapters of his famous work.

This variation in the value that was to be assigned to dreams was closely related to the problem of 'interpreting' them. Important consequences were in general to be expected from dreams. But dreams were not all immediately comprehensible and it was impossible to tell whether a particular unintelligible dream might not be making some important announcement. This provided an incentive for elaborating a method by which the unintelligible content of a dream might be replaced by one that was comprehensible and significant. In the later years of antiquity Artemidorus of Daldis was regarded as the greatest authority on the interpretation of dreams, and the survival of his exhaustive work must compensate us for the loss of the other writings on the same subject.¹

The pre-scientific view of dreams adopted by the peoples of antiquity was certainly in complete harmony with their view of the universe in general, which led them to project into the external world as realities things which in fact enjoyed reality only within their own minds. Moreover, their view of dreams took into account the principal impression produced upon the waking mind in the morning by what is left of a dream in the memory: an impression of something alien, arising from another world and contrasting with the remaining contents of the mind. Incidentally, it would be a mistake to suppose that the theory of the supernatural origin of dreams is without its supporters in our own days. We may leave on one side pietistic and mystical writers, who, indeed, are perfectly justified in remaining in occupation of what is left of the once wide domain of the supernatural so long as that field is not conquered by scientific explanation. But apart from them, one comes across clear-headed men, without any extravagant ideas, who seek to support their religious faith in the existence and activity of superhuman spiritual forces precisely by the inexplicable nature of the phenomena of dreaming. (Cf. Haffner, 1887.) The high esteem in which dream-life is held by some schools of philosophy (by the followers of Schelling, for instance) is clearly an echo of the divine nature of dreams which was undisputed in antiquity. Nor are discussions of the premonitory character of dreams and their power to foretell the future at an end. For attempts at giving a psychological explanation have been inadequate to cover the material collected, however decidedly the sympathies of those of a scientific cast of mind may incline against accepting any such beliefs.

¹ For the further history of dream-interpretation in the Middle Ages see Diepgen (1912) and the monographs of Förster (1910 and 1911), Gotthard (1912), etc. Dream-interpretation among the Jews has been discussed by Almoli (1848), Amram (1901), and Löwinger (1908); also, quite recently and taking account of psycho-analytic findings, by Lauer (1913). Information upon dream-interpretation among the Arabs has been given by Drexel (1909), Schwarz (1913) and the missionary Tfinkdji (1913); among the Japanese by Miura (1906) and Iwaya (1902); among the Chinese by Secker (1909-10); and among the people of India by Negelein (1912).

It is difficult to write a history of the scientific study of the problems of dreams because, however valuable that study may have been at a few points, no line of advance in any particular direction can be traced. No foundation has been laid of secure findings upon which a later investigator might build; but each new writer examines the same problems afresh and begins again, as it were, from the beginning. If I attempted to take those who have written on the question in chronological order and to give a summary of their views upon the problems of dreams, I should have to abandon any hope of giving a comprehensive general picture of the present state of knowledge of the subject. I have therefore chosen to frame my account according to topics rather than authors and, as I raise each dream problem in turn, I shall bring forward whatever material the literature contains for its solution.

Since, however, it has been impossible for me to cover the whole of the literature of the subject, widely scattered as it is and trenching upon many other fields, I must ask my readers to be satisfied so long as no fundamental fact and no important point of view is overlooked in my description.

Until recently most writers on the subject have felt obliged to treat sleep and dreams as a single topic, and as a rule they have dealt in addition with analogous conditions on the fringe of pathology, and dream-like states, such as hallucinations, visions and so on. The latest works, on the contrary, show a preference for a restricted theme and take as their subject, perhaps, some isolated question in the field of dream-life. I should be glad to see in this change of attitude the expression of a conviction that in such obscure matters it will only be possible to arrive at explanations and agreed results by a series of detailed investigations. A piece of detailed research of that kind, predominantly psychological in character, is all I have to offer in these pages. I have had little occasion to deal with the problem of sleep, for that is essentially a problem of physiology, even though one of the characteristics of the state of sleep must be that it brings about modifications in the conditions of functioning of the mental apparatus. The literature on the subject of sleep is accordingly disregarded in what follows.

The questions raised by a scientific enquiry into the phenomena of dreams as such may be grouped under the headings which follow, though a certain amount of overlapping can not be avoided.

(A)

THE RELATION OF DREAMS TO WAKING LIFE

The unsophisticated waking judgement of someone who has just woken from sleep assumes that his dreams, even if they did not themselves come from another world, had at all events carried him off into another world. The old physiologist Burdach (1838, 499), to whom we owe a careful and shrewd account of the phenomena of dreams, has given expression to this conviction in a much-quoted passage: 'In dreams, daily life, with its labours and pleasures, its joys and pains, is never repeated. On the contrary, dreams have as their very aim to free us from it. Even when our whole mind has been filled with something, when we are torn by some deep sorrow or when all our intellectual power is absorbed in some problem, a dream will do no more than enter into the tone of our mood and represent reality in symbols.' I. H. Fichte (1864, 1, 541), in the same sense, actually speaks of 'complementary dreams' and describes them as one of the secret benefactions of the self-healing nature of the spirit. Strümpell (1877, 16) writes to similar effect in his study on the nature and origin of dreams a work which is widely and deservedly held in high esteem: 'A man who dreams is removed from the world of waking consciousness.' So too (*ibid.*, 17): 'In dreams our memory of the ordered contents of waking consciousness and of its normal behaviour is as good as completely lost.' And again (*ibid.*, 19) he writes that 'the mind is cut off in dreams, almost without memory, from the ordinary content and affairs of waking life.'

The preponderant majority of writers, however, take a contrary view of the relation of dreams to waking life. Thus Haffner (1887, 245): 'In the first place, dreams carry on waking life. Our dreams regularly attach themselves to the ideas that have been in our consciousness shortly before. Accurate observation will almost always find a thread which connects a dream with the experiences of the previous day.' Weygandt (1893, 6) specifically contradicts Burdach's statement which I have just quoted: 'For it may often, and apparently in the majority of dreams, be observed that they actually lead us back to ordinary life instead of freeing us from it.' Maury (1878, 51) advances a concise formula: 'Nous rêvons de ce que nous avons vu, dit, désiré ou fait'¹; while Jessen, in his book on psychology (1855, 530), remarks at somewhat greater length: 'the content of a dream is invariably more or less determined by the individual personality of the dreamer, by his age, sex, class, standard of education and habitual way of living, and by the events and experiences of his whole previous life.'

¹ ['We dream of what we have seen, said, desired or done.']

The most uncompromising attitude on this question is adopted by J. G. E. Maass, the philosopher (1805), quoted by Winterstein (1912): 'Experience confirms our view that we dream most frequently of the things on which our warmest passions are centred. And this shows that our passions must have an influence on the production of our dreams. The ambitious man dreams of the laurels he has won (or imagines he has won) or of those he has still to win; while the lover is busied in his dreams with the object of his sweet hopes. . . . All the sensual desires and repulsions that slumber in the heart can, if anything sets them in motion, cause a dream to arise from the ideas that are associated with them or cause those ideas to intervene in a dream that is already present.'

The same view was taken in antiquity on the dependence of the content of dreams upon waking life. Radestock (1879, 134) tells us how before Xerxes started on his expedition against Greece, he was given sound advice of a discouraging kind but was always urged on again by his dreams; whereupon Artabanus, the sensible old Persian interpreter of dreams, observed to him pertinently that as a rule dream-pictures contain what the waking man already thinks.

Lucretius' didactic poem *De rerum natura* contains the following passage (IV, 962):

Et quo quisque fere studio devinctus adhaeret
aut quibus in rebus multum sumus ante morat
atque in ea ratione fuit contenta magis mens,
in somnis eadem plerumque videmur obire;
causidici causas agere et componere leges,
induperatores pugnare ac proelia obire . . .¹

¹ ['And whatever be the pursuit to which one clings with devotion, whatever the things on which we have been occupied much in the past, the mind being thus more intent upon that pursuit, it is generally the same things that we seem to encounter in dreams: pleaders to plead their cause and collate laws, generals to contend and engage battle . . .']

Cicero (*De divinatione*, II, lxxvii, 140) writes to exactly the same effect as Maury so many years later: 'Maximeque reliquiae rerum earum moventur in animis et agitantur de quibus vigilantes aut cogitavimus aut egimus.' ¹

The contradiction between these two views upon the relation between dream-life and waking life seems in fact insoluble. It is therefore relevant at this point to recall the discussion of the subject by Hildebrandt (1875, 8 ff.), who believes that it is impossible to describe the characteristics of dreams at all except by means of 'a series of contrasts which seem to sharpen into contradictions'. 'The first of these contrasts', he writes, 'is afforded on the one hand by the completeness with which dreams are secluded and separated from real and actual life and on the other hand by their constant encroachment upon each other and their constant mutual dependence. A dream is something completely severed from the reality experienced in waking life, something, as one might say, with an hermetically sealed existence of its own, and separated from real life by an impassable gulf. It sets us free from reality, extinguishes our normal memory of it and places us in another world and in a quite other life-story which in essentials has nothing to do with our real one. . . .' Hildebrandt goes on to show how when we fall asleep our whole being with all its forms of existence 'disappears, as it were, through an invisible trap-door'. Then, perhaps, the dreamer may make a sea-voyage to St. Helena in order to offer Napoleon, who is a prisoner there, a choice bargain in Moselle wines. He is received most affably by the ex-Emperor and feels almost sorry when he wakes and the interesting illusion is destroyed. But let us compare the situation in the dream, proceeds Hildebrandt, with reality. The dreamer has never been a wine-merchant and has never wished to be. He has never gone on a sea-voyage, and if he did, St. Helena would be the last place he would choose to go to. He nourishes no sympathetic feelings whatever towards Napoleon, but on the contrary a fierce patriotic hatred. And, on top of all the rest, the dreamer was not even born when Napoleon died on the island; so that to have any personal relations with him was beyond the bounds of possibility. Thus the dream experience appears as something alien inserted between two sections of life which are perfectly continuous and consistent with each other.

¹ ['Then especially do the remnants of our waking thoughts and deeds move and stir within the soul.']

‘And yet’, continues Hildebrandt, ‘what appears to be the contrary of this is equally true and correct. In spite of everything, the most intimate relationship goes hand in hand, I believe, with the seclusion and separation. We may even go so far as to say that whatever dreams may offer, they derive their material from reality and from the intellectual life that revolves around that reality. . . . Whatever strange results they may achieve, they can never in fact get free from the real world; and their most sublime as well as their most ridiculous structures must always borrow their basic material either from what has passed before our eyes in the world of the senses or from what has already found a place somewhere in the course of our waking thoughts - in other words from what we have already experienced either externally or internally.’

(B)

THE MATERIAL OF DREAMS - MEMORY IN DREAMS

All the material making up the content of a dream is in some way derived from experience, that is to say, has been reproduced or remembered in the dream - so much at least we may regard as an undisputed fact. But it would be a mistake to suppose that a connection of this kind between the content of a dream and reality is bound to come to light easily, as an immediate result of comparing them. The connection requires, on the contrary, to be looked for diligently, and in a whole quantity of cases it may long remain hidden. The reason for this lies in a number of peculiarities which are exhibited by the faculty of memory in dreams and which, though generally remarked upon, have hitherto resisted explanation. It will be worth while to examine these characteristics more closely.

It may happen that a piece of material occurs in the content of a dream which in the waking state we do not recognize as forming a part of our knowledge or experience. We remember, of course, having dreamt the thing in question, but we cannot remember whether or when we experienced it in real life. We are thus left in doubt as to the source which has been drawn upon by the dream and are tempted to believe that dreams have a power of independent production. Then at last, often after a long interval, some fresh experience recalls the lost memory of the other event and at the same time reveals the source of the dream. We are thus driven to admit that in the dream we knew and remembered something which was beyond the reach of our waking memory.¹

A particularly striking example of this is given by Delboeuf from his own experience. He saw in a dream the courtyard of his house covered with snow and found two small lizards half-frozen and buried under it. Being an animal-lover, he picked them up, warmed them and carried them back to the little hole in the masonry where they belonged. He further gave them a few leaves of a small fern which grew on the wall and of which, as he knew, they were very fond. In the dream he knew the name of the plant: *Asplenium ruta muralis*. The dream proceeded and, after a digression, came back to the lizards. Delboeuf then saw to his astonishment two new ones which were busy on the remains of the fern. He then looked round him and saw a fifth and then a sixth lizard making their way to the hole in the wall, until the whole roadway was filled with a procession of lizards, all moving in the same direction . . . and so on.

¹ [Footnote added 1914:] Vaschide (1911) remarks that it has often been observed that in dreams people speak foreign language more fluently and correctly than in waking life.

When he was awake, Delbouf knew the Latin names of very few plants and an *Asplenium* was not among them. To his great surprise he was able to confirm the fact that a fern of this name actually exists. Its correct name is *Asplenium ruta muraria*, which had been slightly distorted in the dream. It was hardly possible that this could be a coincidence; and it remained a mystery to Delboeuf how he had acquired his knowledge of the name '*Asplenium*' in his dream.

The dream occurred in 1862. Sixteen years later, while the philosopher was on a visit to one of his friends, he saw a little album of pressed flowers of the sort that are sold to foreigners as mementoes in some parts of Switzerland. A recollection began to dawn on him - he opened the herbarium, found the *Asplenium* of his dream and saw its Latin name written underneath it in his own handwriting. The facts could now be established. In 1860 (two years before the lizard dream) a sister of this same friend had visited Delboeuf on her honeymoon. She had with her the album, which was to be a gift to her brother, and Delboeuf took the trouble to write its Latin name under each dried plant, at the dictation of a botanist.

Good luck, which made this example so well worth recording, enabled Delboeuf to trace yet another part of the content of the dream to its forgotten source. One day in 1877 he happened to take up an old volume of an illustrated periodical and in it he found a picture of the whole procession of lizards which he had dreamed of in 1862. The volume was dated 1861 and Delbouf remembered having been a subscriber to the paper from its first number.

The fact that dreams have at their command memories which are inaccessible in waking life is so remarkable and of such theoretical importance that I should like to draw still more attention to it by relating some further 'hypermnestic' dreams. Maury tells us how for some time the word 'Mussidan' kept coming into his head during the day. He knew nothing about it except that it was the name of a town in France. One night he dreamt that he was talking to someone who told him he came from Mussidan, and who, on being asked where that was, replied that it was a small town in the Department of Dordogne. When he woke up, Maury had no belief in the information given him in the dream; he learnt from a gazetteer, however, that it was perfectly correct. In this case the fact of the dream's superior knowledge was confirmed, but the forgotten source of that knowledge was not discovered.

Jessen (1855, 551) reports a very similar event in a dream dating from remoter times: 'To this class belongs among others a dream of the elder Scaliger (quoted by Hennings, 1784, 300) who wrote a poem in praise of the famous men of Verona. A man who called himself Brugnolus appeared to him in a dream and complained that he had been overlooked. Although Scaliger could not remember having ever heard of him, he wrote some verses on him. His son learnt later in Verona that someone named Brugnolus had in fact been celebrated there as a critic.'

The Marquis d'Hervey de St. Denys, quoted by Vaschide (1911, 232 f.), describes a hypermnestic dream which has a special peculiarity, for it was followed by another dream which completed the recognition of what was at first an unidentified memory: 'I once dreamt of a young woman with golden hair, whom I saw talking to my sister while showing her some embroidery. She seemed very familiar to me in the dream and I thought I had seen her very often before. After I woke up, I still had her face very clearly before me but I was totally unable to recognize it. I then went to sleep once more and the dream-picture was repeated. . . . But in this second dream I spoke to the fair-haired lady and asked her if I had not had the pleasure of meeting her before somewhere. "Of course," she replied, "don't you remember the *plage* at Pornic?" I immediately woke up again and I was then able to recollect clearly all the details associated with the attractive vision in the dream.'

The same author (quoted again by Vaschide, *ibid.*, 233-4-) tells how a musician of his acquaintance once heard in a dream a tune which seemed to him entirely new. It was not until several years later that he found the same tune in an old collected volume of musical pieces, though he still could not remember ever having looked through it before.

I understand that Myers has published a whole collection of hypermnesic dreams of this kind in the *Proceedings of the Society for Psychical Research*; but these are unluckily inaccessible to me.

No one who occupies himself with dreams can, I believe, fail to discover that it is a very common event for a dream to give evidence of knowledge and memories which the waking subject is unaware of possessing. In my psycho-analytic work with nervous patients, of which I shall speak later, I am in a position several times a week to prove to patients from their dreams that they are really quite familiar with quotations, obscene words and so on, and make use of them in their dreams, though they have forgotten them in their waking life. I will add one more innocent case of hypermnesia in a dream, because of the great ease with which it was possible to trace the source of the knowledge that was accessible only in the dream.

One of my patients dreamt in the course of a fairly lengthy dream that he had ordered a '*Kontuszówka*' while he was in a cafe. After telling me this, he asked me what a '*Kontuszówka*' was, as he had never heard the name. I was able to tell him in reply that it was a Polish liqueur, and that he could not have invented the name as it had long been familiar to me from advertisements on the hoardings. At first he would not believe me; but some days later, after making his dream come true in a cafe, he noticed the name on a hoarding at a street corner which he must have gone past at least twice a day for several months.

I have noticed myself from my own dreams how much it is a matter of chance whether one discovers the source of particular elements of a dream. Thus, for several years before completing this book, I was pursued by the picture of a church tower of very simple design, which I could not remember ever having seen. Then I suddenly recognized it, with absolute certainty, at a small station on the line between Salzburg and Reichenhall. That was during the second half of the eighteen nineties and I had travelled over the line for the first time in 1886. During later years, when I was already deeply absorbed in the study of dreams, the frequent recurrence in my dreams of the picture of a particular unusual-looking place became a positive nuisance to me. In a specific spatial relation to myself, on my left-hand side, I saw a dark space out of which there glimmered a number of grotesque sandstone figures. A faint recollection, which I was unwilling to credit, told me it was the entrance to a beer-cellar. But I failed to discover either the meaning of the dream-picture or its origin. In 1907 I happened to be in Padua, which, to my regret, I had not been able to visit since 1895. My first visit to that lovely University town had been a disappointment, as I had not been able to see Giotto's frescoes in the Madonna dell'Arena. I had turned back half-way along the street leading there, on being told that the chapel was closed on that particular day. On my second visit, twelve years later, I decided to make up for this and the first thing I did was to set off towards the Arena chapel. In the street leading to it, on my left-hand side as I walked along and in all probability at the point at which I had turned back in 1895, I came upon the place I had seen so often in my dreams, with the sandstone figures that formed part of it. It was in fact the entrance to the garden of a restaurant.

One of the sources from which dreams derive material for reproduction - material which is in part neither remembered nor used in the activities of waking thought - is childhood experience. I will quote only a few of the authors who have noticed and stressed this fact.

Hildebrandt (1875, 23): 'I have already expressly admitted that dreams sometimes bring back to our minds, with a wonderful power of reproduction, very remote and even forgotten events from our earliest years.'

Strümpell (1877, 40): 'The position is even more remarkable when we observe how dreams sometimes bring to light, as it were, from beneath the deepest piles of débris under which the earliest experiences of youth are buried in later times, pictures of particular localities, things or people, completely intact and with all their original freshness. This is not limited to experiences which created a lively impression when they occurred or enjoy a high degree of psychical importance and return later in a dream as genuine recollections at which waking consciousness will rejoice. On the contrary, the depths of memory in dreams also include pictures of people, things, localities and events dating from the earliest times, which either never possessed any psychical importance or more than a slight degree of vividness, or which have long since lost what they may have possessed of either, and which consequently seem completely alien and unknown alike to the dreaming and waking mind till their earlier origin has been discovered.'

Volkelt (1875, 119): 'It is especially remarkable how readily memories of childhood and youth make their way into dreams. Dreams are continually reminding us of things which we have ceased to think of and which have long ceased to be important to us.'

Since dreams have material from childhood at their command, and since, as we all know, that material is for the most part blotted out by gaps in our conscious faculty of memory, these circumstances give rise to interesting hypermnesic dreams, of which I will once more give a few examples.

Maury (1878, 92) relates how when he was a child he used often to go from Meaux, which was his birthplace, to the neighbouring village of Trilport, where his father was superintending the building of a bridge. One night in a dream he found himself in Trilport and was once more playing in the village street. A man came up to him who was wearing a sort of uniform. Maury asked him his name and he replied that he was called G. and was a watchman at the bridge. Maury awoke feeling sceptical as to the correctness of the memory, and asked an old maid-servant, who had been with him since his childhood, whether she could remember a man of that name. 'Why, yes', was the reply, 'he was the watchman at the bridge when your father was building it.'

Maury (*ibid.*, 143-4) gives another equally well corroborated example of the accuracy of a memory of childhood emerging in a dream. It was dreamt by a Monsieur F., who as a child had lived at Montbrison. Twenty-five years after leaving it, he decided to revisit his home and some friends of the family whom he had not since met. During the night before his departure he dreamt that he was already at Montbrison and, near the town, met a gentleman whom he did not know by sight but who told him he was Monsieur T., a friend of his father's. The dreamer was aware that when he was a child he had known someone of that name, but in his waking state no longer remembered what he looked like. A few days later he actually reached Montbrison, found the locality which in his dream had seemed unknown to him, and there met a gentleman whom he at once recognized as the Monsieur T. in the dream. The real person, however, looked much older than he had appeared in the dream.

At this point I may mention a dream of my own, in which what had to be traced was not an impression but a connection. I had a dream of someone who I knew in my dream was the doctor in my native town. His face was indistinct, but was confused with a picture of one of the masters at my secondary school, whom I still meet occasionally. When I woke up I could not discover what connection there was between these two men. I made some enquiries from my mother, however, about this doctor who dated back to the earliest years of my childhood, and learnt that he had only one eye. The schoolmaster whose figure had covered that of the doctor in the dream, was also one-eyed. It was thirty-eight years since I had seen the doctor, and so far as I know I had never thought of him in my waking life, though a scar on my chin might have reminded me of his attentions.

A number of writers, on the other hand, assert that elements are to be found in most dreams, which are derived from the very last few days before they were dreamt; and this sounds like an attempt to counterbalance the laying of too much weight upon the part played in dream-life by experiences in childhood. Thus Robert (1886, 46) actually declares that normal dreams are as a rule concerned only with the impressions of the past few days. We shall find, however, that the theory of dreams constructed by Robert makes it essential for him to bring forward the most recent impressions and leave the oldest out of sight. None the less the fact stated by him remains correct, as I am able to confirm from my own investigations. An American writer, Nelson, is of the opinion that the impressions most frequently employed in a dream arise from the day next but one before the dream occurs, or from the day preceding that one - as though the impressions of the day *immediately* before the dream were not sufficiently attenuated or remote.

Several writers who are anxious not to cast doubts on the intimate connection between the content of dreams and waking life have been struck by the fact that impressions with which waking thoughts are intensely occupied only appear in dreams after they have been pushed somewhat aside by the workings of daytime thought. Thus, after the death of someone dear to them, people do not as a rule dream of him to begin with, while they are overwhelmed by grief (Delage, 1891). On the other hand one of the most recent observers, Miss Hallam (Hallam and Weed, 1896, 410-11), has collected instances to the contrary, thus asserting the right of each of us to psychological individualism in this respect.

The third, most striking and least comprehensible characteristic of memory in dreams is shown in the *choice* of material reproduced. For what is found worth remembering is not, as in waking life, only what is most important, but on the contrary what is most indifferent and insignificant as well. On this point I will quote those writers who have given the strongest expression to their astonishment.

Hildebrandt (1875, 11): 'For the remarkable thing is that dreams derive their elements not from major and stirring events nor the powerful and compelling interests of the preceding day, but from incidental details, from the worthless fragments, one might say, of what has been recently experienced or of the remoter past. A family bereavement, which has moved us deeply and under whose immediate shadow we have fallen asleep late at night, is blotted out of our memory till with our first waking moment it returns to it again with disturbing violence. On the other hand, a wart on the forehead of a stranger whom we met in the street and to whom we owe no second thought after passing him *has* a part to play in our dream. . . .'

Strümpell (1877, 39): 'There are cases in which the analysis of a dream shows that some of its components are indeed derived from experiences of the previous day or its predecessor, but experiences so unimportant and trivial from the point of view of waking consciousness that they were forgotten soon after they occurred. Experiences of this kind include, for instance, remarks accidentally overheard, or another person's actions inattentively observed, or passing glimpses of people or things, or odd fragments of what one has read, and so on.'

Havelock Ellis (1899, 727): 'The profound emotions of waking life, the questions and problems on which we spread our chief voluntary mental energy, are not those which usually present themselves at once to dream consciousness. It is, so far as the immediate past is concerned, mostly the trifling, the incidental, the "forgotten" impressions of daily life which reappear in our dreams. The psychic activities that are awake most intensely are those that sleep most profoundly.'

Binz (1878, 44-5) actually makes this particular peculiarity of memory in dreams the occasion for expressing his dissatisfaction with the explanations of dreams which he himself has supported: 'And the natural dream raises similar problems. Why do we not always dream of the mnemonic impressions of the day we have just lived through? Why do we often, without any apparent motive, plunge instead into the remote and almost extinct past? Why does consciousness so often in dreams receive the impression of *indifferent* mnemonic images, while the brain cells, just where they carry the most sensitive marks of what has been experienced, lie for the most part silent and still, unless they have been stirred into fresh activity shortly before, during waking life?'

It is easy to see how the remarkable preference shown by the memory in dreams for indifferent, and consequently unnoticed, elements in waking experience is bound to lead people to overlook in general the dependence of dreams upon waking life and at all events to make it difficult in any particular instance to prove that dependence. Thus Miss Whiton Galkins (1893, 315), in her statistical study of her own and her collaborator's dreams, found that in eleven per cent of the total there was no visible connection with waking life. Hildebrandt (1875,) is unquestionably right in asserting that we should be able to explain the genesis of every dream-image if we devoted enough time and trouble to tracing its origin. He speaks of this as 'an exceedingly laborious and thankless task. For as a rule it ends in hunting out every kind of utterly worthless psychical event from the remotest corners of the chambers of one's memory, and in dragging to light once again every kind of completely indifferent moment of the past from the oblivion in which it was buried in the very hour, perhaps, after it occurred.' I can only regret that this keen-sighted author allowed himself to be deterred from following the path which had this inauspicious beginning; if he had followed it, it would have led him to the very heart of the explanation of dreams.

The way in which the memory behaves in dreams is undoubtedly of the greatest importance for any theory of memory in general. It teaches us that 'nothing which we have once mentally possessed can be entirely lost' (Scholz, 1893, 59); or, as Delboeuf puts it, 'que toute impression même la plus insignifiante, laisse une trace inaltérable, indéfiniment susceptible de reparaitre au jour.' This is a conclusion to which we are also driven by many pathological phenomena of mental life. Certain theories about dreams which we shall mention later seek to account for their absurdity and incoherence by a partial forgetting of what we know during the day. When we bear in mind the extraordinary efficiency that we have just seen exhibited by memory in dreams we shall have a lively sense of the contradiction which these theories involve.

It might perhaps occur to us that the phenomenon of dreaming could be reduced entirely to that of memory: dreams, it might be supposed, are a manifestation of a reproductive activity which is at work even in the night and which is an end in itself. This would tally with statements such as those made by Pilcz (1899), according to which there is a fixed relation observable between the time at which a dream occurs and its content-impressions from the remotest past being reproduced in dreams during deep sleep, while more recent impressions appear towards morning. But views of this sort are inherently improbable owing to the manner in which dreams deal with the material that is to be remembered. Strümpell rightly points out that dreams do not reproduce experiences. They take one step forward, but the next step in the chain is omitted, or appears in an altered form, or is replaced by something entirely extraneous. Dreams yield no more than *fragments* of reproductions; and this is so general a rule that theoretical conclusions may be based on it. It is true that there are exceptional cases in which a dream repeats an experience with as much completeness as is attainable by our waking memory. Delboeuf tells how one of his university colleagues had a dream which reproduced in all its details a dangerous carriage accident he had had, with an almost miraculous escape. Miss Calkins (1893) mentions two dreams whose content was an exact reproduction of an event of the previous day, and I shall myself have occasion later to report an example I came across of a childhood experience re-appearing in a dream without modification.¹

¹ [Footnote added 1909:] Subsequent experience leads me to add that it by no means rarely happens that innocent and unimportant actions of the previous day are repeated in a dream: such, for instance, as packing a trunk, preparing food in the kitchen, and so on. What the dreamer is himself stressing in dreams of this kind is not, however, the content of the memory but the fact of its being 'real': 'I really *did* do all that yesterday.'

(C)

THE STIMULI AND SOURCES OF DREAMS

There is a popular saying that 'dreams come from indigestion' and this helps us to see what is meant by the stimuli and sources of dreams. Behind these concepts lies a theory according to which dreams are a result of a disturbance of sleep: we should not have had a dream unless something disturbing had happened during our sleep, and the dream was a reaction to that disturbance.

Discussions upon the exciting causes of dreams occupy a very large space in the literature of the subject. The problem could obviously only arise after dreams had become a subject of biological investigation. The ancients, who believed that dreams were inspired by the gods, had no need to look around for their stimulus: dreams emanated from the will of divine or daemonic powers and their content arose from the knowledge or purpose of those powers. Science was immediately faced by the question of whether the stimulus to dreaming was always the same or whether there could be many kinds of such stimuli; and this involved the consideration of whether the explanation of the causation of dreams fell within the province of psychology or rather of physiology. Most authorities seem to agree in assuming that the causes that disturb sleep - that is, the sources of dreaming - may be of many kinds and that somatic stimuli and mental excitations alike may come to act as instigators of dreams. Opinions differ widely, however, in the preference they show for one or the other source of dreams and in the order of importance which they assign to them as factors in the production of dreams.

Any complete enumeration of the sources of dreams leads to a recognition of four kinds of source; and these have also been used for the classification of dreams themselves. They are: (1) external (objective) sensory excitations; (2) internal (subjective) sensory excitations; (3) internal (organic) somatic stimuli; and (4) purely psychical sources of stimulation.

1. EXTERNAL SENSORY STIMULI

The younger Strümpell, the son of the philosopher whose book on dreams has already given us several hints upon their problems, published a well-known account of his observations upon one of his patients who was afflicted with general anaesthesia of the surface of his body and paralysis of several of his higher sense organs. If the few of this man's sensory channels which remained open to the external world were closed, he would fall asleep. Now when we ourselves wish to go to sleep we are in the habit of trying to produce a situation similar to that of Strümpell's experiment. We close our most important sensory channels, our eyes, and try to protect the other senses from all stimuli or from any modification of the stimuli acting on them. We then fall asleep, even though our plan is never completely realized. We cannot keep stimuli completely away from our sense organs nor can we completely suspend the excitability of our sense organs. The fact that a fairly powerful stimulus will awaken us at any time is evidence that 'even in sleep the soul is in constant contact with the extracorporeal world'. The sensory stimuli that reach us during sleep may very well become sources of dreams.

Now there are a great number of such stimuli, ranging from the unavoidable ones which the state of sleep itself necessarily involves or must tolerate from time to time, to the accidental, rousing stimuli which may or do put an end to sleep. A bright light may force its way into our eyes, or a noise may make itself heard, or some strong-smelling substance may stimulate the mucous membrane of our nose. By unintentional movements during our sleep we may uncover some part of our body and expose it to sensations of chill, or by a change in posture we may ourselves bring about sensations of pressure or contact. We may be stung by a gnat, or some small mishap during the night may impinge upon several of our senses at once. Attentive observers have collected a whole series of dreams in which there has been such a far-reaching correspondence between a stimulus noticed on waking and a portion of the content of the dream that it has been possible to identify the stimulus as the source of the dream .

I will quote from Jessen (1855, 527 f.) a collection of dreams of this kind which may be traced back to objective, and more or less accidental, sensory stimulation.

'Every noise that is indistinctly perceived arouses corresponding dream-images. A peal of thunder will set us in the midst of a battle; the crowing of a cock may turn into a man's cry of terror; the creaking of a door may produce a dream of burglars. If our bed-clothes fall off in the night, we may dream, perhaps, of walking about naked or of falling into water. If we are lying cross-wise in bed and push our feet over the edge, we may dream that we are standing on the brink of a frightful precipice or that we are falling over a cliff. If our head happens to get under the pillow, we dream of being beneath a huge overhanging rock which is on the point of burying us under its weight. Accumulations of semen lead to lascivious dreams, local pains produce ideas of being ill-treated, attacked or injured. . . .'

'Meier (1758, 33) once dreamt that he was overpowered by some men who stretched him out on his back on the ground and drove a stake into the earth between his big toe and the next one. While he was imagining this in the dream he woke up and found that a straw was sticking between his toes. On another occasion, according to Hennings (1784, 258), when Meier had fastened his shirt rather tight round his neck, he dreamt that he was being hanged. Hoffbauer dreamt when he was a young man of falling down from a high wall, and when he woke up found that his bedstead had collapsed and that he had really fallen on to the floor. . . . Gregory reports that once, when he was lying with his feet on a hot-water bottle, he dreamt he had climbed to the top of Mount Etna and that the ground there was intolerably hot. Another man, who was sleeping with a hot poultice on his head, dreamt that he was being scalped by a band of Red Indians; while a third, who was wearing a damp night-shirt, imagined that he was being dragged through a stream. An attack of gout that came on suddenly during sleep caused the patient to believe he was in the hands of the Inquisition and being tortured on the rack. (Macnish.)'

The argument based on the similarity between the stimulus and the content of the dream gains in strength if it is possible deliberately to convey a sensory stimulus to the sleeper and produce in him a dream corresponding to that stimulus. According to Macnish (loc. cit.), quoted by Jessen (1855, 529), experiments of this sort had already been made by Girou de Buzareingues. 'He left his knee uncovered and dreamt that he was travelling at night in a mail coach. He remarks upon this that travellers will no doubt be aware how cold one's knees become at night in a coach. Another time he left his head uncovered at the back and dreamt that he was taking part in a religious ceremony in the open air. It must be explained that in the country in which he lived it was the custom always to keep the head covered except in circumstances such as these.'

Maury (1878) brings forward some new observations of dreams produced in himself. (A number of other experiments were unsuccessful.)

(1) His lips and the tip of his nose were tickled with a feather. - He dreamt of a frightful form of torture: a mask made of pitch was placed on his face and then pulled off, so that it took his skin off with it,

(2) A pair of scissors was sharpened on a pair of pliers. -He heard bells pealing, followed by alarm-bells, and he was back in the June days of 1848.

(3) He was given some eau-de-cologne to smell. -He was in Cairo, in Johann Maria Farina's shop. Some absurd adventures followed, which he could not reproduce.

(4) He was pinched lightly on the neck. - He dreamt he was being given a mustard plaster and thought of the doctor who had treated him as a child.

(5) A hot iron was brought close to his face. - He dreamt that the '*chauffeurs*'¹ had made their way into the house and were forcing its inhabitants to give up their money by sticking their feet into braziers of hot coal. The Duchess of Abrantes, whose secretary he was in the dream, then appeared.

(8) A drop of water was dropped on his forehead. - He was in Italy, was sweating violently and was drinking white Orvieto wine.

(9) Light from a candle was repeatedly shone upon him through a sheet of red paper. - He dreamt of the weather and of the heat, and was once again in a storm he had experienced in the English Channel.

¹ The '*chauffeurs*' were bands of robbers in La Vendée, who made use of the method of torture described above.

Other attempts at producing dreams experimentally have been reported by Hervey de Saint-Denys, Weygandt (1893), and others.

Many writers have commented upon 'the striking facility with which dreams are able to weave a sudden impression from the world of the senses into their own structure so that it comes as what appears to be a pre-arranged catastrophe that has been gradually led up to.' (Hildebrandt, 1875.) 'In my youth', the author goes on, 'I used to make use of an alarm-clock in order to be up regularly at a fixed hour. It must have happened hundreds of times that the noise produced by this instrument fitted into an ostensibly lengthy and connected dream as though the whole dream had been leading up to that one event and had reached its appointed end in what was a logically indispensable climax.'

I shall quote three of these alarm-clock dreams presently in another connection.

Volkelt (1875, 108 f.) writes: 'A composer once dreamt that he was giving a class and was trying to make a point clear to his pupils. When he had done, he turned to one of the boys and asked him if he had followed. The boy shouted back like a lunatic: "Oh ja! " He began to reprove the boy angrily for shouting, but the whole class broke out into cries first of "Orja!", then of "Eurjo!" and finally of "Feuerjo!" At this point he was woken up by actual cries of "Feuerjo!" in the street.'

Garnier (1865) tells how Napoleon I was woken by a bomb-explosion while he was asleep in his carriage. He had a dream that he was once more crossing the Tagliamento under the Austrian bombardment, and at last started up with a cry: 'We are undermined!'

A dream dreamt by Maury (1878, 161) has become famous. He was ill and lying in his room in bed, with his mother sitting beside him, and dreamt that it was during the Reign of Terror. After witnessing a number of frightful scenes of murder, he was finally himself brought before the revolutionary tribunal. There he saw Robespierre, Marat, Fouquier-Tinville and the rest of the grim heroes of those terrible days. He was questioned by them, and, after a number of incidents which were not retained in his memory, was condemned, and led to the place of execution surrounded by an immense mob. He climbed on to the scaffold and was bound to the plank by the executioner. It was tipped up. The blade of the guillotine fell. He felt his head being separated from his body, woke up in extreme anxiety and found that the top of the bed had fallen down and had struck his cervical vertebrae just in the way in which the blade of the guillotine would actually have struck them.

This dream was the basis of an interesting discussion between Le Lorrain (1894) and Egger (1895) in the *Revue philosophique*. The question raised was whether and how it was possible for a dreamer to compress such an apparently superabundant quantity of material into the short period elapsing between his perceiving the rousing stimulus and his waking.

Examples of this kind leave an impression that of all the sources of dreams the best confirmed are objective sensory stimuli during sleep. Moreover they are the only sources whatever taken into account by laymen. If an educated man, who is unacquainted with the literature of dreams, is asked how dreams arise, he will infallibly answer with a reference to some instance he has come across in which a dream was explained by an objective sensory stimulus discovered after waking. Scientific enquiry, however, cannot stop there. It finds an occasion for further questions in the observed fact that the stimulus which impinges on the senses during sleep does not appear in the dream in its *real* shape but is replaced by another image in some way related to it. But the relation connecting the stimulus of the dream to the dream which is its result is, to quote Maury's words (1854, 72); 'une affinité quelconque, mais qui n'est pas unique et exclusive.'¹ Let us consider in this connection three of Hildebrandt's alarm-clock dreams (1875, 37 f.). The question they raise is why the same stimulus should have provoked three such different dreams and why it should have provoked these rather than any other.

¹ ['An affinity of some kind, but one which is not unique and exclusive.']

'I dreamt, then, that one spring morning I was going for a walk and was strolling through the green fields till I came to a neighbouring village, where I saw the villagers in their best clothes, with hymn-books under their arms, flocking to the church. Of course! It was Sunday, and early morning service would soon be beginning. I decided I would attend it; but first, as I was rather hot from walking, I went into the churchyard which surrounded the church, to cool down. While I was reading some of the tombstones, I heard the bell-ringer climbing up the church tower and at the top of it I now saw the little village bell which would presently give the signal for the beginning of devotions. For quite a while it hung there motionless, then it began to swing, and suddenly its peal began to ring out clear and piercing - so clear and piercing that it put an end to my sleep. But what was ringing was the alarm-clock.

'Here is another instance. It was a bright winter's day and the streets were covered with deep snow. I had agreed to join a party for a sleigh-ride; but I had to wait a long time before news came that the sleigh was at the door. Now followed the preparations for getting in - the fur rug spread out, the foot muff put ready- and at last I was sitting in my seat. But even then the moment of departure was delayed till a pull at the reins gave the waiting horses the signal. Then off they started, and, with a violent shake, the sleigh bells broke into their familiar jingle - with such violence, in fact, that in a moment the cobweb of my dream was torn through. And once again it was only the shrill sound of the alarm-clock.

'And now yet a third example. I saw a kitchen-maid, carrying several dozen plates piled on one another, walking along the passage to the dining-room. The column of china in her arms seemed to me in danger of losing its balance. "Take care," I exclaimed, "or you'll drop the whole load." The inevitable rejoinder duly followed: she was quite accustomed to that kind of job, and so on. And meanwhile my anxious looks followed the advancing figure. Then - just as I expected -she stumbled at the threshold and the fragile crockery slipped and rattled and clattered in a hundred pieces on the floor. But the noise continued without ceasing, and soon it seemed no longer to be a clattering; it was turning into a ringing - and the ringing, as my waking self now became aware, was only the alarm-clock doing its duty.'

The question of why the mind mistakes the nature of objective sensory stimuli in dreams receives almost the same answer from Strümpell (1877) as from Wundt (1874): the mind receives stimuli that reach it during sleep under conditions favourable to the formation of illusions. A sense impression is recognized by us and correctly interpreted - that is, it is placed in the group of memories to which, in accordance with all our previous experiences, it belongs - provided the impression is sufficiently strong, clear and lasting and provided we have sufficient time at our disposal for considering the matter. If these conditions are not fulfilled, we mistake the object which is the source of the impression: we form an illusion about it. 'If someone goes for a walk in the open country and has in indeterminate perception of a distant object, he may at first believe it to be a horse.' On a closer view he may be led to interpret it as a cow lying down, and the image may finally resolve itself definitely into a group of people sitting on the ground. The impressions received by the mind from external stimuli during sleep are of a similarly indeterminate nature; and on their basis the mind forms illusions, since a greater or smaller number of mnemonic images are aroused by the impression and it is through them that it acquires its psychical value. From *which* of the many groups of memories concerned the related images shall be aroused and *which* of the possible associative connections shall accordingly be put into action - these questions too, on Strümpell's theory, are indeterminable and are, as it were, left open to the arbitrary decision of the mind.

At this point we are faced with a choice between two alternatives. We may admit it as a fact that it is impossible to follow the laws governing the formation of dreams any further; and we may accordingly refrain from enquiring whether there may not be other determinants governing the interpretation put by the dreamer upon the illusion called up by the sense-impression. Or, on the other hand, we may have a suspicion that the sensory stimulus which impinges on the sleeper plays only a modest part in generating his dream and that other factors determine the choice of the mnemonic images which are to be aroused in him. In fact, if we examine Maury's experimentally produced dreams (which I have related in such detail for this very reason), we shall be tempted to say that the experiment in fact accounts for the origin of only one element of the dreams; the rest of their content seems too self-contained, too definite in its details, to be explicable solely by the necessity for fitting in with the element experimentally introduced from outside. Indeed, one begins to have doubts about the illusion theory and about the power of objective impressions to give a shape to dreams when one finds that those impressions are sometimes subjected in dreams to the most peculiar and far-fetched interpretations. Thus Simon (1888) tells us of a dream in which he saw some gigantic figures seated at table and clearly heard the frightful snapping noise made by their jaws coming together as they chewed. When he awoke he heard the beat of a horse's hooves galloping past his window. The noise made by the horse's hooves may have suggested ideas from a group of memories connected with *Gulliver's Travels* - the giants of Brobdingnag and the virtuous Houyhnhnms - if I may venture on an interpretation without the dreamer's assistance. Is it not probable, then, that the choice of such an unusual group of memories as these was facilitated by motives other than the objective stimulus alone!¹

¹ [Footnote added 1911:] The appearance of gigantic figures in a dream gives grounds for supposing that some scene from the dreamer's childhood is involved. - [Added 1925:] Incidentally, the interpretation given in the text, pointing to a reminiscence of *Gulliver's Travels*, is a good example of what an interpretation ought *not* to be. The interpreter of a dream should not give free play to his own ingenuity and neglect the dreamer's associations.

2. INTERNAL (SUBJECTIVE) SENSORY EXCITATIONS

In spite of any objections to the contrary, it has to be admitted that the part played by objective sensory excitations during sleep in provoking dreams remains indisputable. And if such stimuli may appear, from their nature and frequency, insufficient to explain *every* dream-image, we shall be encouraged to seek for other sources of dreams analogous to them in their operation. I cannot say when the idea first cropped up of taking *internal* (subjective) excitations of the sense organs into account alongside of the *external* sensory stimuli. It is, however, the case that this is done, more or less explicitly, in all the more recent discussions of the aetiology of dreams. 'An essential part is also played, I believe', writes Wundt (1874, 657), 'in the production of the illusions that occur in dreams by the subjective visual and auditory sensations which are familiar to us in the waking state as the formless areas of luminosity which become visible to us when our field of vision is darkened, as ringing or buzzing in the ears, and so on. Especially important among these are the subjective excitations of the retina. It is in this way that is to be explained the remarkable tendency of dreams to conjure up before the eyes similar or identical objects in large numbers. We see before us innumerable birds or butterflies or fishes or coloured beads or flowers, etc. Here the luminous dust in the darkened field of vision has taken on a fantastic shape, and the numerous specks of which it consists are incorporated into the dream as an equal number of separate images; and these, on account of their mobility, are regarded as *moving* objects. -This is no doubt also the basis of the great fondness shown by dreams for animal figures of every sort; for the immense variety of such forms can adjust itself easily to the particular form assumed by the subjective luminous images.'

As sources of dream-images, subjective sensory excitations have the obvious advantage of not being dependent, like objective ones, upon external chance. They are ready to hand, as one might say, whenever they are needed as an explanation. But they are at a disadvantage compared with objective sensory stimuli in that the part they play in instigating a dream is scarcely or not at all open to confirmation, as is the case with objective stimuli, by observation and experiment. The chief evidence in favour of the power of subjective sensory excitations to instigate dreams is provided by what are known as 'hypnagogic hallucinations', or, to use Johannes Müller's term (1826), 'imaginative visual phenomena'. These are images, often very vivid and rapidly changing, which are apt to appear - quite habitually, in some people - during the period of falling asleep; and they may also persist for a time after the eyes have been opened. Maury, who was subject to them in a high degree, has made an exhaustive examination of them and maintains (as did Müller before him) their connection and indeed their identity with dream-images. In order to produce them, he says (Maury, 1878, 59 f.), a certain amount of mental passivity, a relaxation of the strain of attention, is necessary. It is enough, however, to fall into a lethargic state of this kind for no more than a second (provided that one has the necessary predisposition) in order to have a hypnagogic hallucination. After this one may perhaps wake up again and the process may be repeated several times until one finally falls asleep. Maury found that if he then woke up once more after not too long an interval, he was able to detect in his dream the same images that had floated before his eyes as hypnagogic hallucinations before he fell asleep. (Ibid., 134 f.) This was the case on one occasion with a number of grotesque figures with distorted faces and strange *coiffures* which pestered him with extreme pertinacity while he was going to sleep and which he remembered having dreamt about after he woke. Another time, when he was suffering from hunger owing to having put himself on a light diet, he had a hypnagogic vision of a plate and a hand armed with a fork which was helping itself to some of the food from the plate. In the dream which followed he was sitting at a well spread table and heard the noise made by the diners with their forks. Yet another time, when he went to sleep with his eyes in an irritated and painful state, he had a hypnagogic hallucination of some microscopically small signs which he could only decipher one by one with the greatest difficulty; he was woken from his sleep an hour later and remembered a dream in which here was an open book printed in very small type which he was reading painfully.

Auditory hallucinations of words, names, and so on can also occur hypnagogically in the same way as visual images, and may then be repeated in a dream - just as an overture announces the principal themes which are to be heard in the opera that is to follow.

A more recent observer of hypnagogic hallucinations, G. Trumbull Ladd (1892), has followed the same lines as Müller and Maury. After some practice he succeeded in being able to wake himself suddenly without opening his eyes, from two to five minutes after gradually falling asleep. He thus had an opportunity of comparing the retinal sensations which were just disappearing with the dream-images persisting in his memory. He declares that it was possible in every case to recognize an internal relation between the two, for the luminous points and lines of the idioretinal light provided, as it were, an outline drawing or diagram of the figures mentally perceived in the dream. For instance, an arrangement of the luminous points in the retina in parallel lines corresponded to a dream in which he had been seeing, clearly spread out in front of him, some lines of print which he was engaged in reading. Or, to use his own words, 'the clearly printed page which I was reading in my dream faded away into an object that appeared to my waking consciousness like a section of an actual page of print when seen through an oval hole in a piece of paper at too great a distance to distinguish more than an occasional fragment of a word, and even that dimly.' Ladd is of opinion (though he does not underestimate the part played in the phenomenon by central factors) that scarcely a single visual dream, occurs without the participation of material provided by intraocular retinal excitation. This applies especially to dreams occurring soon after falling asleep in a dark room, while the source of stimulus for dreams occurring in the morning shortly before waking is the objective light which penetrates the eyes in a room that is growing light. The changing, perpetually shifting character of the excitation of the idioretinal light corresponds precisely to the constantly moving succession of images shown us by our dreams. No one who attaches importance to these observations of Ladd's will underestimate the part played in dreams by these subjective sources of stimulation, for, as we know, visual images constitute the principal component of our dreams. The contributions from the other senses, except for that of hearing, are intermittent and of less importance.

3. INTERNAL ORGANIC SOMATIC STIMULI

Since we are now engaged in looking for sources of dreams inside the organism instead of outside it, we must bear in mind that almost all our internal organs, though they give us scarcely any news of their working so long as they are in a healthy state, become a source of what are mainly distressing sensations when they are in what we describe as states of excitation, or during illnesses. These sensations must be equated with the sensory or painful stimuli reaching us from the outside. The experience of ages is reflected in - to take an example - Strümpell's remarks on the subject (1877, 107): 'During sleep the mind attains a far deeper and wider sensory consciousness of somatic events than during the waking state. It is obliged to receive and be affected by impressions of stimuli from parts of the body and from changes in the body of which it knows nothing when awake.' So early a writer as Aristotle regarded it as quite possible that the beginnings of an illness might make themselves felt in dreams before anything could be noticed of it in waking life, owing to the magnifying effect produced upon impressions by dreams. (See above, p. 518.) Medical writers, too, who were certainly far from believing in the prophetic power of dreams, have not disputed their significance as premonitors of illness. (Cf. Simon, 1888, 31, and many earlier writers.)¹

¹ [Footnote added 1914:] Apart from the diagnostic value ascribed to dreams (e.g. in the works of Hippocrates), their *therapeutic* importance in antiquity must also be borne in mind. In Greece there were dream oracles, which were regularly visited by patients in search of recovery. A sick man would enter the temple of Apollo or Aesculapius, would perform various ceremonies there, would be purified by lustration, massage and incense, and then, in a state of exaltation, would be stretched on the skin of a ram that had been sacrificed. He would then fall asleep and would dream of the remedies for his illness. These would be revealed to him either in their natural form or in symbols and pictures which would afterwards be interpreted by the priests. For further information upon therapeutic dreams among the Greeks see Lehmann (1908, 1, 74), Bouché-Leclercq (1879-1882), Hermann (1858, §41, 262 ff., and 1882, §38, 356), Böttinger (1795, 163 ff.), Lloyd (1877), Döllinger (1857, 130).

Instances of the diagnostic power of dreams seem to be vouched for in more recent times. Thus Tissié (1898, 62 f.) quotes from Artigues (1884, 43) the story of a forty-three-year old woman, who, while apparently in perfect health, was for some years tormented by anxiety-dreams. She was then medically examined and found to be in the early stages of an affection of the heart, to which she eventually succumbed.

Pronounced disorders of the internal organs obviously act as instigators of dreams in a whole number of cases. The frequency of anxiety-dreams in diseases of the heart and lungs is generally recognized. Indeed, this side of dream-life is placed in the foreground by so many authorities that I am content with a mere reference to the literature: Radestock, Spitta, Maury, Simon (1888), Tissié. Tissié is even of the opinion that the particular organ affected gives a characteristic impress to the content of the dream. Thus the dreams of those suffering from diseases of the heart are usually short and come to a terrifying end at the moment of waking; their content almost always includes a situation involving a horrible death. Sufferers from diseases of the lungs dream of suffocation, crowding and fleeing, and are remarkably subject to the familiar nightmare. (It may be remarked, incidentally, that Börner (1855) has succeeded in provoking the latter experimentally by lying on his face or covering the respiratory apertures.) In the case of digestive disorders dreams contain ideas connected with enjoyment of food or disgust. Finally, the influence of sexual excitement on the content of dreams can be adequately appreciated by everyone from his own experience and provides the theory that dreams are instigated by organic stimuli with its most powerful support.

No one, moreover, who goes through the literature of the subject can fail to notice that some writers, such as Maury and Weygandt (1893), were led to the study of dream problems by the effect of their own illnesses upon the content of their dreams.

Nevertheless, though these facts are established beyond a doubt, their importance for the study of the sources of dreams is not so great as might have been hoped. Dreams are phenomena which occur in healthy people - perhaps in everyone, perhaps every night - and it is obvious that organic illness cannot be counted among its indispensable conditions. And what we are concerned with is not the origin of certain special dreams but the source that instigates the ordinary dreams of normal people.

We need only go a step further, however, in order to come upon a source of dreams more copious than any we have so far considered, one indeed which seems as though it could never run dry. If it is established that the interior of the body when it is in a diseased state becomes a source of stimuli for dreams, and if we admit that during sleep the mind, being diverted from the external world, is able to pay more attention to the interior of the body, then it seems plausible to suppose that the internal organs do not need to be diseased before they can cause excitations to reach the sleeping mind - excitations which are somehow turned into dream-images. While we are awake we are aware of a diffuse general sensibility or coenaesthesia, but only as a vague quality of our mood; to this feeling, according to medical opinion, all the organic systems contribute a share. At night, however, it would seem that this same feeling, grown into a powerful influence and acting through its various components, becomes the strongest and at the same time the commonest source for instigating dream-images. If this is so, it would only remain to investigate the laws according to which the organic stimuli turn into dream-images.

We have here reached the theory of the origin of dreams which is preferred by all the medical authorities. The obscurity in which the centre of our being (the '*moi splanchnique*', as Tissié calls it) is veiled from our knowledge and the obscurity surrounding the origin of dreams tally too well not to be brought into relation to each other. The line of thought which regards vegetative organic sensation as the constructor of dreams has, moreover, a particular attraction for medical men since it allows of a single aetiology for dreams and mental diseases, whose manifestations have so much in common; for coenaesthetic changes and stimuli arising from the internal organs are also held largely responsible for the origin of the psychoses. It is not surprising, therefore, that the origin of the theory of somatic stimulation may be traced back to more than one independent source.

The line of argument developed by the philosopher Schopenhauer in 1851 has had a decisive influence on a number of writers. Our picture of the universe, in his view, is arrived at by our intellect taking the impressions that impinge on it from outside and remoulding them into the forms of time, space and causality. During the daytime the stimuli from the interior of the organism, from the sympathetic nervous system, exercise at the most an unconscious effect upon our mood. But at night, when we are no longer deafened by the impressions of the day, those which arise from within are able to attract attention just as at night we can hear the murmuring of a brook which is drowned by daytime noise. But how is the intellect to react to these stimuli otherwise than by carrying out its own peculiar function on them? The stimuli are accordingly remodelled into forms occupying space and time and obeying the rules of causality, and thus dreams arise. Scherner (1861) and after him Volkelt (1875) endeavoured subsequently to investigate in more detail the relation between somatic stimuli and dream-images, but I shall postpone my consideration of these attempts till we reach the section dealing with the various theories about dreams.

Krauss, the psychiatrist, in an investigation carried through with remarkable consistency, traces the origin alike of dreams and of deliria and delusions to the same factor, namely to organically determined sensations. It is scarcely possible to think of any part of the organism which might not be the starting-point of a dream or of a delusion. Organically determined sensations 'may be divided into two classes: (1) those constituting the general mood (coenaesthesia) and (2) the specific sensations immanent in the principal systems of the vegetative organism. Of these latter five groups are to be distinguished: (a) muscular, (b) respiratory, (c) gastric, (d) sexual and (e) peripheral sensations.' Krauss supposes that the process by which dream-images arise on the basis of somatic stimuli is as follows. The sensation that has been aroused evokes a cognate image, in accordance with some law of association. It combines with the image into an organic structure, to which, however, consciousness reacts abnormally. For it pays no attention to the *sensation*, but directs the whole of it to the accompanying *images* - which explains why the true facts were for so long misunderstood. Krauss has a special term for describing this process: the 'trans-substantiation' of sensations into dream-images.

The influence of organic somatic stimuli upon the formation of dreams is almost universally accepted to-day; but the question of the laws that govern the relation between them is answered in very various ways, and often by obscure pronouncements. On the basis of the theory of somatic stimulation, dream-interpretation is thus faced with the special problem of tracing back the content of a dream to the organic stimuli which caused it; and, if the rules for interpretation laid down by Scherner (1861) are not accepted, one is often faced with the awkward fact that the only thing that reveals the existence of the organic stimulus is precisely the content of the dream itself.

There is a fair amount of agreement, however, over the interpretation of various forms of dreams that are described as 'typical', because they occur in large numbers of people and with very similar content. Such are the familiar dreams of falling from a height, of teeth falling out, of flying and of embarrassment at being naked or insufficiently clad. This last dream is attributed simply to the sleeper's perceiving that he has thrown off his bedclothes in his sleep and is lying exposed to the air. The dream of teeth falling out is traced back to a 'dental stimulus', though this does not necessarily imply that the excitation of the teeth is a pathological one. According to Strümpell the flying dream is the image which is found appropriate by the mind as an interpretation of the stimulus produced by the rising and sinking of the lobes of the lungs at times when cutaneous sensations in the thorax have ceased to be conscious: it is this latter circumstance that leads to the feeling which is attached to the idea of floating. The dream of falling from a height is said to be due to an arm falling away from the body or a flexed knee being suddenly extended at a time when the sense of cutaneous pressure is beginning to be no longer conscious; the movements in question cause the tactile sensations to become conscious once more, and the transition to consciousness is represented psychically by the dream of falling (*ibid.*, 118). The obvious weakness of these attempted explanations, plausible though they are, lies in the fact that, without any other evidence, they can make successive hypotheses that this or that group of organic sensations enters or disappears from mental perception, till a constellation has been reached which affords an explanation of the dream. I shall later have occasion to return to the question of typical dreams and their origin.

Simon (1888, 34 f.) has attempted to deduce some of the rules governing the way in which organic stimuli determine the resultant dreams by comparing a series of similar dreams. He asserts that if an organic apparatus which normally plays a part in the expression of an emotion is brought by some extraneous cause during sleep into the state of excitation which is usually produced by the emotion, then a dream will arise which will contain images appropriate to the emotion in question. Another rule lays it down that if during sleep an organ is in a state of activity, excitation or disturbance, the dream will produce images related to the performance of the function which is discharged by the organ concerned. Mourly Vold (1896) has set out to prove experimentally in one particular field the effect on the production of dreams which is asserted by the theory of somatic stimulation. His experiment consisted in altering the position of a sleeper's limbs and comparing the resultant dreams with the alterations made. He states his findings as follows:

- (1) The position of a limb in the dream corresponds approximately to its position in reality. Thus, we dream of the limb being in a static condition when it is so actually.
- (2) If we dream of a limb moving, then one of the positions passed through in the course of completing the movement in variably corresponds to the limb's actual position.
- (3) The position of the dreamer's own limb may be ascribed in the dream to some other person.
- (4) The dream may be of the movement in question being *hindered*.
- (5) The limb which is in the position in question may appear in the dream as an animal or monster, in which case a certain analogy is established between them.
- (6) The position of a limb may give rise in the dream to thoughts which have some connection with the limb. Thus, if the fingers are concerned, we dream of numbers.

I should be inclined to conclude from findings such as these that even the theory of somatic stimulation has not succeeded in completely doing away with the apparent absence of determination in the choice of what dream-images are to be produced.¹

¹ [Footnote added 1914:] This author has since produced a two-volume report on his experiments (1910 and 1912), which is referred to below.

4. PSYCHICAL SOURCES OF STIMULATION

When we were dealing with the relations of dreams to waking life and with the material of dreams, we found that the most ancient and the most recent students of dreams were united in believing that men dream of what they do during the daytime and of what interests them while they are awake. Such an interest, carried over from waking life into sleep, would not only be a mental bond, a link between dreams and life, but would also provide us with a further source of dreams and one not to be despised. Indeed, taken in conjunction with the interests that develop during sleep - the stimuli that impinge on the sleeper - it might be enough to explain the origin of all dream-images. But we have also heard the opposite asserted, namely that dreams withdraw the sleeper from the interests of daytime and that, as a rule, we only start dreaming of the things that have most struck us during the day, after they have lost the spice of actuality in waking life. Thus at every step we take in our analysis of dream-life we come to feel that it is impossible to make generalizations without covering ourselves by such qualifying phrases as 'frequently', 'as a rule' or 'in most cases', and without being prepared to admit the validity of exceptions.

If it were a fact that waking interests, along with internal and external stimuli during sleep, sufficed to exhaust the aetiology of dreams, we ought to be in a position to give a satisfactory account of the origin of every element of a dream: the riddle of the sources of dreams would be solved, and it would only remain to define the share taken respectively by psychical and somatic stimuli in any particular dream. Actually no such complete explanation of a dream has ever yet been achieved, and anyone who has attempted it has found portions (and usually very numerous portions) of the dream regarding whose origin he could find nothing to say. Daytime interests are clearly not such far-reaching psychical sources of dreams as might have been expected from the categorical assertions that everyone continues to carry on his daily business in his dreams.

No other psychical sources of dreams are known. So it comes about that all the explanations of dreams given in the literature of the subject - with the possible exception of Scherner's, which will be dealt with later - leave a great gap when it comes to assigning an origin for the ideational images which constitute the most characteristic material of dreams. In this embarrassing situation, a majority of the writers on the subject have tended to reduce to a minimum the part played by psychical factors in instigating dreams, since those factors are so hard to come at. It is true that they divide dreams into two main classes - those 'due to nervous stimulation' and those 'due to association', of which the latter have their source exclusively in reproduction (cf. Wundt, 1874, 657 f.). Nevertheless they cannot escape a doubt 'whether any dream can take place without being given an impetus by some somatic stimulus' (Volkelt, 1875, 127). It is difficult even to give a description of purely associative dreams. 'In associative dreams proper, there can be no question of any such solid core. Even the very centre of the dream is only loosely put together. The ideational processes, which in any dream are ungoverned by reason or common sense, are here no longer even held together by my relatively important somatic or mental excitations, and are thus abandoned to their own kaleidoscopic changes and to their own jumbled confusion.' (Ibid., 118.) Wundt (1874, 656-7), too, seeks to minimize the psychical factor in the instigation of dreams. He declares that there seems to be no justification for regarding the phantasms of dreams as pure hallucinations; most dream-images are probably in fact illusions, since they arise from faint sense-impressions, which never cease during sleep. Weygandt (1893, 17) has adopted this same view and made its application general. He asserts of *all* dream-images 'that their primary causes are sensory stimuli and that only later do reproductive associations become attached to them'. Tissié (1898, 183) goes even further in putting a limit to the psychical sources of stimulation: 'Les rêves d'origine absolument psychique n'existent pas'; and (ibid., 6) 'les pensées de nos rêves nous viennent du dehors. . . .'¹

¹ ['Dreams of purely psychical origin do not exist.' 'The thoughts in our dreams reach us from outside.']

Those writers who, like that eminent philosopher Wundt, take up a middle position do not fail to remark that in most dreams somatic stimuli and the psychical instigators (whether unknown or recognized as daytime interests) work in co-operation.

We shall find later that the enigma of the formation of dreams can be solved by the revelation of an unsuspected psychical source of stimulation. Meanwhile we shall feel no surprise at the over-estimation of the part played in forming dreams by stimuli which do not arise from mental life. Not only are they easy to discover and even open to experimental confirmation; but the somatic view of the origin of dreams is completely in line with the prevailing trend of thought in psychiatry to-day. It is true that the dominance of the brain over the organism is asserted with apparent confidence. Nevertheless, anything that might indicate that mental life is in any way independent of demonstrable organic changes or that its manifestations are in any way spontaneous alarms the modern psychiatrist, as though a recognition of such things would inevitably bring back the days of the Philosophy of Nature, and of the metaphysical view of the nature of mind. The suspicions of the psychiatrists have put the mind, as it were, under tutelage, and they now insist that none of its impulses shall be allowed to suggest that it has any means of its own. This behaviour of theirs only shows how little trust they really have in the validity of a causal connection between the somatic and the mental. Even when investigation shows that the primary exciting cause of a phenomenon is psychical, deeper research will one day trace the path further and discover an organic basis for the mental event. But if at the moment we cannot see beyond the mental, that is no reason for denying its existence.

(D)

WHY DREAMS ARE FORGOTTEN AFTER WAKING

It is a proverbial fact that dreams melt away in the morning. They can, of course, be remembered; for we only know dreams from our memory of them after we are awake. But we very often have a feeling that we have only remembered a dream in part and that there was more of it during the night; we can observe, too, how the recollection of a dream, which was still lively in the morning, will melt away, except for a few small fragments, in the course of the day; we often know we have dreamt, without knowing *what* we have dreamt; and we are so familiar with the fact of dreams being liable to be forgotten, that we see no absurdity in the possibility of someone having had a dream in the night and of his not being aware in the morning either of what he has dreamt or even of the fact that he has dreamt at all. On the other hand, it sometimes happens that dreams show an extraordinary persistence in the memory. I have analysed dreams in my patients which occurred twenty-five and more years earlier; and I can remember a dream of my own separated by at least thirty-seven years from to-day and yet as fresh as ever in my memory. All of this is very remarkable and not immediately intelligible.

The most detailed account of the forgetting of dreams is the one given by Strümpell. It is evidently a complex phenomenon, for Strümpell traces it back not to a single cause but to a whole number of them.

In the first place, all the causes that lead to forgetting in waking life are operative for dreams as well. When we are awake we regularly forget countless sensations and perceptions at once, because they were too weak or because the mental excitation attaching to them was too slight. The same holds good of many dream-images: they are forgotten because they are too weak, while stronger images adjacent to them are remembered. The factor of intensity, however, is certainly not in itself enough to determine whether a dream-image shall be recollected. Strümpell admits, as well as other writers (e.g. Calkins, 1893, 312), that we often forget dream-images which we know were very vivid, while a very large number which are shadowy and lacking in sensory force are among those retained in the memory. Moreover when we are awake we tend easily to forget an event which occurs only once and more readily to notice what can be perceived repeatedly.¹ Now most dream-images are unique experiences; and that fact will contribute impartially towards making us forget all dreams. Far more importance attaches to a third cause of forgetting. If sensations, ideas, thoughts, and so on, are to attain a certain degree of susceptibility to being remembered, it is essential that they should not remain isolated but should be arranged in appropriate concatenations and groupings. If a short line of verse is divided up into its component words and these are mixed up, it becomes very hard to remember. 'If words are properly arranged and put into the relevant order, one word will help another, and the whole, being charged with meaning, will be easily taken up by the memory and retained for a long time. It is in general as difficult and unusual to retain what is nonsensical as it is to retain what is confused and disordered.' Now dreams are in most cases lacking in intelligibility and orderliness. The compositions which constitute dreams are barren of the qualities which would make it possible to remember them, and they are forgotten because as a rule they fall to pieces a moment later. Radestock (1879, 168), however, claims to have observed that it is the most peculiar dreams that are best remembered, and this, it must be admitted, would scarcely tally with what has just been said.

Strümpell believes that certain other factors derived from the relation between dreaming and waking life are of still greater importance in causing dreams to be forgotten. The liability of dreams to be forgotten by waking consciousness is evidently only the counterpart of the fact which has been mentioned earlier that dreams scarcely ever take over ordered recollections from waking life, but only details selected from them, which they tear from the psychical context in which they are usually remembered in the waking state. Thus dream-compositions find no place in the company of the psychical sequences with which the mind is filled. There is nothing that can help us to remember them. 'In this way dream-structures are, as it were, lifted above the floor of our mental life and float in psychical space like clouds in the sky, scattered by the first breath of wind.' (Strümpell, 1877, 87.) After waking, moreover, the world of the senses presses forward and at once takes possession of the attention with a force which very few dream-images can resist; so that here too we have another factor tending in the same direction. Dreams give way before the impressions of a new day just as the brilliance of the stars yields to the light of the sun.

¹ Dreams that recur periodically have often been observed. Cf. the collection given by Chabaneix (1897).

Finally, there is another fact to be borne in mind as likely to lead to dreams being forgotten, namely that most people take very little interest in their dreams. Anyone, such as a scientific investigator, who pays attention to his dreams over a period of time will have more dreams than usual - which no doubt means that he remembers his dreams with greater ease and frequency.

Two further reasons why dreams should be forgotten, which Benini quotes as having been brought forward by Bonatelli as additions to those mentioned by Strümpell, seem in fact to be already covered by the latter. They are (1) that the alteration in coenaesthesia between the sleeping and waking states is unfavourable to reciprocal reproduction between them; and (2) that the different arrangement of the ideational material in dreams makes them untranslatable, as it were, for waking consciousness.

In view of all these reasons in favour of dreams being forgotten, it is in fact (as Strümpell himself insists) very remarkable that so many of them are retained in the memory. The repeated attempts by writers on the subject to lay down the rules governing the recollection of dreams amount to an admission that here too we are faced by something puzzling and unexplained. Certain particular characteristics of the recollection of dreams have been rightly emphasized recently (cf. Radestock, 1879, and Tissié, 1898), such as the fact that when a dream seems in the morning to have been forgotten, it may nevertheless be recollected during the course of the day, if its content, forgotten though it is, is touched upon by some chance perception.

But the recollection of dreams in general is open to an objection which is bound to reduce their value very completely in critical opinion. Since so great a proportion of dreams is lost altogether, we may well doubt whether our memory of what is left of them may not be falsified.

These doubts as to the accuracy of the reproduction of dreams are also expressed by Strümpell (1877): 'Thus it may easily happen that waking consciousness unwittingly makes interpolations in the memory of a dream: we persuade ourselves that we have dreamt all kinds of things that were not contained in the actual dreams.'

Jessen (1855, 547) writes with special emphasis on this point: 'Moreover, in investigating and interpreting coherent and consistent dreams a particular circumstance must be borne in mind which, as it seems to me, has hitherto received too little attention. In such cases the truth is almost always obscured by the fact that when we recall dreams of this kind to our memory we almost always - unintentionally and without noticing the fact - fill in the gaps in the dream-images. It is seldom or never that a coherent dream was in fact as coherent as it seems to us in memory. Even the most truth-loving of men is scarcely able to relate a noteworthy dream without some additions or embellishments. The tendency of the human mind to see everything connectedly is so strong that in memory it unwittingly fills in any lack of coherence there may be in an incoherent dream.'

Some remarks made by Egger, though they were no doubt arrived at independently, read almost like a translation of this passage from Jessen: '... L'observation des rêves a ses difficultés spéciales et le seul moyen d'éviter tout erreur en pareille matière est de confier au papier sans le moindre retard ce que l'on vient d'éprouver et de remarquer; sinon, l'oubli vient vite ou total ou partiel; l'oubli total est sans gravité; mais l'oubli partiel est perfide; car si l'on se met ensuite à raconter ce que l'on n'a pas oublié, on est exposé à compléter par imagination les fragments incohérents et disjointes fournis par la mémoire . . .; on devient artiste à son insu, et le récit périodiquement répété s'impose à la créance de son auteur, qui, de bonne foi, le présente comme un fait authentique, dûment établi selon les bonnes méthodes. . . .'¹

Very similar ideas are expressed by Spitta (1882, 338), who seems to believe that it is not until we try to reproduce a dream that we introduce order of any kind into its loosely associated elements: we 'change things that are merely juxtaposed into sequences or causal chains, that is to say, we introduce a process of logical connection which is lacking in the dream.'

Since the only check that we have upon the validity of our memory is objective confirmation, and since that is unobtainable for dreams, which are our own personal experience and of which the only source we have is our recollection, what value can we still attach to our memory of dreams?

¹ ['There are peculiar difficulties in observing dreams, and the only way of escaping all errors in such matters is to put down upon paper with the least possible delay what we have just experienced or observed. Otherwise forgetfulness, whether total or partial, quickly supervenes. Total forgetfulness is not serious; but partial forgetfulness is treacherous. For if we then proceed to give an account of what we have not forgotten, we are liable to fill in from our imagination the incoherent and disjointed fragments furnished by memory. . . . We unwittingly become creative artists; and the tale, if it is repeated from time to time, imposes itself on its author's own belief, and he ends by offering it in good faith as an authentic fact duly and legitimately established.']

(E)

THE DISTINGUISHING PSYCHOLOGICAL CHARACTERISTICS OF DREAMS

Our scientific consideration of dreams starts off from the assumption that they are products of our own mental activity. Nevertheless the finished dream strikes us as something alien to us. We are so little obliged to acknowledge our responsibility for it that we are just as ready to say '*mir hat geträumt*' ['I had a dream', literally 'a dream came to me'] as '*ich habe geträumt*' ['I dreamt']. What is the origin of this feeling that dreams are extraneous to our minds? In view of our discussion upon the sources of dreams, we must conclude that the strangeness cannot be due to the material that finds its way into their content, since that material is for the most part common to dreaming and waking life. The question arises whether in dreams there may not be modifications in the processes of the mind which produce the impression we are discussing; and we shall therefore make an attempt at drawing a picture of the psychological attributes of dreams.

No one has emphasized more sharply the essential difference between dreaming and waking life or drawn more far-reaching conclusions from it than G. T. Fechner in a passage in his *Elemente der Psychophysik* (1889, 2, 520-1). In his opinion, 'neither the mere lowering of conscious mental life below the main threshold', nor the withdrawal of attention from the influences of the external world, are enough to explain the characteristics of dream-life as contrasted with waking life. He suspects, rather, that *the scene of action of dreams is different from that of waking ideational life*. 'If the scene of action of psychophysical activity were the same in sleeping and waking, dreams could, in my view, only be a prolongation at a lower degree of intensity of waking ideational life and, moreover, would necessarily be of the same material and form. But the facts are quite otherwise.'

It is not clear what Fechner had in mind in speaking of this change of location of mental activity; nor, so far as I know, has anyone else pursued the path indicated by his words. We may, I think, dismiss the possibility of giving the phrase an anatomical interpretation and supposing it to refer to physiological cerebral localization or even to the histological layers of the cerebral cortex. It may be, however, that the suggestion will eventually prove to be sagacious and fertile, if it can be applied to a *mental* apparatus built up of a number of agencies arranged in a series one behind the other.

Other writers have contented themselves with drawing attention to the more tangible of the distinguishing characteristics of dream-life and with taking them as a starting-point for attempts at more far reaching explanations.

It has justly been remarked that one of the principal peculiarities of dream-life makes its appearance during the very process of falling asleep and may be described as a phenomenon heralding sleep. According to Schleiermacher (1862, 351), what characterizes the waking state is the fact that thought-activity takes place in *concepts* and not in *images*. Now dreams think essentially in images; and with the approach of sleep it is possible to observe how, in proportion as voluntary activities become more difficult, involuntary ideas arise, all of which fall into the class of images. Incapacity for ideational work of the kind which we feel as intentionally willed and the emergence (habitually associated with such states of abstraction) of images - these are two characteristics which persevere in dreams and which the psychological analysis of dreams forces us to recognize as essential features of dream-life. We have already seen that these images - hypnagogic hallucinations - are themselves identical in their content with dream-images.¹

¹ [Footnote added 1911:] Silberer (1909) has given some nice examples of the way in which, in a drowsy state, even abstract thoughts become converted into pictorial plastic images which seek to express the same meaning. [Added 1925:] I shall have occasion to return to this discovery in another connection.

Dreams, then, think predominantly in visual images - but not exclusively. They make use of auditory images as well, and, to a lesser extent, of impressions belonging to the other senses. Many things, too, occur in dreams (just as they normally do in waking life) simply as thoughts or ideas - probably, that is to say, in the form of residues of verbal presentations. Nevertheless, what are truly characteristic of dreams are only those elements of their content which behave like images, which are more like perceptions, that is, than they are like mnemonic presentations. Leaving on one side all the arguments, so familiar to psychiatrists, on the nature of hallucinations, we shall be in agreement with every authority on the subject in asserting that dreams *hallucinate* - that they replace thoughts by hallucinations. In this respect there is no distinction between visual and acoustic presentations: it has been observed that if one falls asleep with the memory of a series of musical notes in one's mind, the memory becomes transformed into an hallucination of the same melody; while, if one then wakes up again - and the two states may alternate more than once during the process of dropping asleep - the hallucination gives way in turn to the mnemonic presentation, which is at once fainter and qualitatively different from it.

The transformation of ideas into hallucinations is not the only respect in which dreams differ from corresponding thoughts in waking life. Dreams construct a *situation* out of these images; they represent an event which is actually happening; as Spitta (1882, 145) puts it, they 'dramatize' an idea. But this feature of dream-life can only be fully understood if we further recognize that in dreams - as a rule, for there are exceptions which require special examination - we appear not to *think* but to *experience*; that is to say, we attach complete belief to the hallucinations. Not until we wake up does the critical comment arise that we have not experienced anything but have merely been thinking in a peculiar way, or in other words dreaming. It is this characteristic that distinguishes true dreams from day-dreaming, which is never confused with reality.

Burdach (1838, 502 f.) summarizes the features of dream-life which we have so far discussed in the following words: 'These are among the essential features of dreams: (a) In dreams the subjective activity of our minds appears in an objective form, for our perceptive faculties regard the products of our imagination as though they were sense impressions . . . (b) Sleep signifies an end of the authority of the self. Hence falling asleep brings a certain degree of passivity along with it. . . . The images that accompany sleep can occur only on condition that the authority of the self is reduced.'

The next thing is to try to explain the belief which the mind accords to dream-hallucinations, a belief which can only arise after some kind of 'authoritative' activity of the self has ceased. Strümpell (1877) argues that in this respect the mind is carrying out its function correctly and in conformity with its own mechanism. Far from being mere presentations, the elements of dreams are true and real mental experiences of the same kind as arise in a waking state through the agency of the senses. (Ibid., 34.) The waking mind produces ideas and thoughts in verbal images and in speech; but in dreams it does so in true sensory images. (Ibid., 35.) Moreover, there is a spatial consciousness in dreams, since sensations and images are assigned to an external space, just as they are in waking. (Ibid., 36.) It must therefore be allowed that in dreams the mind is in the same relation to its images and perceptions as it is in waking. (Ibid., 43.) If it is nevertheless in error in so doing, that is because in the state of sleep it lacks the criterion which alone makes it possible to distinguish between sense-perceptions arising from without and from within. It is unable to submit its dream-images to the only tests which could prove their objective reality. In addition to this, it disregards the distinction between images which are only interchangeable *arbitrarily* and cases where the element of arbitrariness is absent. It is in error because it is unable to apply the law of causality to the content of its dreams. (Ibid., 50-1.) In short, the fact of its having turned away from the external world is also the reason for its belief in the subjective world of dreams.

Delboeuf (1885, 84) arrives at the same conclusion after somewhat different psychological arguments. We believe in the reality of dream-images, he says, because in our sleep we have no other impressions with which to compare them, because we are detached from the external world. But the reason why we believe in the truth of these hallucinations is not because it is impossible to put them to the test *within* the dream. A dream can seem to offer us such tests: it can let us touch the rose that we see - and yet we are dreaming. In Delboeuf's opinion there is only one valid criterion of whether we are dreaming or awake, and that is the purely empirical one of the fact of waking up. I conclude that everything I experienced between falling asleep and waking up was illusory, when, on awaking, I find that I am lying undressed in bed. During sleep I took the dream images as real owing to my mental habit (which cannot be put to sleep) of assuming the existence of an external world with which I contrast my own ego.¹

¹ Haffner (1887, 243) attempts, like Delboeuf, to explain the activity of dreaming by the modification which the introduction of an abnormal condition must inevitably produce in the otherwise correct functioning of an intact mental apparatus; but he gives a somewhat different account of that condition. According to him the first mark of a dream is its independence of space and time, i. e. the fact of a presentation being emancipated from the position occupied by the subject in the spatial and temporal order of events. The second basic feature of dreams is connected with this - namely, the fact that hallucinations, phantasies and imaginary combinations are confused with external perceptions. 'All the higher powers of the mind - in particular the formation of concepts and the powers of judgement and inference on the one hand and free self-determination on the other hand - are attached to sensory images and have at all times a background of such images. It follows, therefore, that these higher activities too take their part in the disorderliness of the dream-images. I say "take their part", since in them selves our powers of judgement and of will are in no way altered in sleep. Our activities are just as clear-sighted and just as free as in waking life. Even in his dreams a man cannot violate the laws of thought as such - he cannot, for instance, regard as identical things that appear to him as contraries, and so on. So too in dreams he can only desire what he looks upon as a good (*sub ratione boni*). But the human spirit is led astray in dreams in its *application* of the laws of thought and of will through confusing one idea with another. Thus it comes about that we are guilty of the grossest contradictions in dreams, while at the same time we can make the clearest judgements, draw the most logical inferences and come to the most virtuous and saintly decisions. . . . Lack of orientation is the whole secret of the flights taken by our imagination in dreams, and lack of critical reflection and of communication with other people is the main source of the unbridled extravagance exhibited in dreams by our judgements as well as by our hopes and wishes.' (Ibid., 18.)

Detachment from the external world seems thus to be regarded as the factor determining the most marked features of dream-life. It is therefore worth while quoting some penetrating remarks made long ago by Burdach which throw light on the relations between the sleeping mind and the external world and which are calculated to prevent our setting too great store by the conclusions drawn in the last few pages. 'Sleep', he writes, 'can occur only on condition that the mind is not irritated by sensory stimuli. . . . But the actual 'recondition of sleep is not so much absence of sensory stimuli as absence of interest in them.'¹ Some sense impressions may actually be necessary in order to calm the mind. Thus the miller can only sleep so long as he hears the clacking of his mill; and anyone who feels that burning a night-light is a necessary precaution, finds it impossible to get to sleep in the dark.' (Burdach, 1838, 482.)

'In sleep the mind isolates itself from the external world and withdraws from its own periphery. . . . Nevertheless connection is not broken off entirely. If we could not hear or feel while we were actually asleep, but only after we had woken up, it would be impossible to wake us at all. . . . The persistence of sensation is proved even more clearly by the fact that what rouses us is not always the mere sensory strength of an impression but its psychical context: a sleeping man is not aroused by an indifferent word, but if he is called by name he wakes. . . . Thus the mind in sleep distinguishes between sensations. . . . It is for that reason that the absence of a sensory stimulus can wake a man if it is related to something of ideational importance to him; so it is that the man with the night-light wakes if it is extinguished and the miller is roused if his mill comes to a stop. He is awakened, that is, by the cessation of a sensory activity; and this implies that that activity was perceived by him, but, since it was indifferent, or rather satisfying, did not disturb his mind.' (Ibid., 485-6.)

Even if we disregard these objections - and they are by no means trifling ones -, we shall have to confess that the features of dream-life which we have considered hitherto, and which have been ascribed to its detachment from the external world, do not account completely for its strange character. For it should be possible otherwise to turn the hallucinations in a dream back into ideas, and its situations into thoughts, and in that way to solve the problem of dream-interpretation. And that in fact is what we are doing when, after waking, we reproduce a dream from memory; but, whether we succeed in making this re-translation wholly or only in part, the dream remains no less enigmatic than before.

¹ [Footnote added 1914:] Cf. the '*désintéressé*' which Claparède (1905, 306 f.) regards as the mechanism of falling asleep.

And indeed all the authorities unhesitatingly assume that yet other and more deep-going modifications of the ideational material of waking life take place in dreams. Strümpell (1877, 27-8) has endeavoured to put his finger on one such modification in the following passage: 'With the cessation of sensory functioning and of normal vital consciousness, the mind loses the soil in which its feelings, desires, interests and activities are rooted. The psychical states, too - feelings, interests, judgements of value - which are linked to mnemonic images in waking life, are subjected to . . . an obscuring pressure, as a result of which their connection with those images is broken; perceptual images of things, persons, places, events and actions in waking life are reproduced separately in great numbers, but none of them carries its *psychical value* along with it. That value is detached from them and they thus float about in the mind at their own sweet will. . . .' According to Strümpell, the fact of images being denuded of their psychical value (which in turn goes back to detachment from the external world) plays a principal part in creating the impression of strangeness which distinguishes dreams from actual life in our memory.

We have seen that falling asleep at once involves the loss of one of our mental activities, namely our power of giving intentional guidance to the sequence of our ideas. We are now faced by the suggestion, which is in any case a plausible one, that the effects of the state of sleep may extend over *all* the faculties of the mind. Some of these seem to be entirely suspended; but the question now arises whether the rest continue to operate normally and whether under such conditions they are *capable* of normal work. And here it may be asked whether the distinguishing features of dreams cannot be explained by the lowering of psychical efficiency in the sleeping state - a notion which finds support in the impression made by dreams on our waking judgement. Dreams are disconnected, they accept the most violent contradictions without the least objection, they admit impossibilities, they disregard knowledge which carries great weight with us in the daytime, they reveal us as ethical and moral imbeciles. Anyone who when he was awake behaved in the sort of way that is shown in situations in dreams would be considered insane. Anyone who when he was awake talked in the sort of way that people talk in dreams or described the sort of thing that happens in dreams would give us the impression of being muddle-headed or feeble minded. It seems to be no more than putting the truth into words when we express our very low opinion of mental activity in dreams and assert that in dreams the higher intellectual faculties in particular are suspended or at all events gravely impaired.

The authorities display unusual unanimity - exceptions will be treated later - in expressing opinions of this kind on dreams; and these judgements lead directly to a particular theory or explanation of dream-life. But it is time for me to leave generalities and to give instead a series of quotations from various writers - philosophers and physicians - upon the psychological characteristics of dreams.

According to Lemoine (1855), the 'incoherence' of dream images is the one essential characteristic of dreams.

Maury (1878, 163) agrees with him: 'Il n'y a pas de rêves absolument raisonnables et qui ne contiennent quelque incohérence, quelque anachronisme, quelque absurdité.' ¹

Spitta quotes Hegel as saying that dreams are devoid of all objectives and reasonable coherence.

Dugas writes: 'Le rêve c'est l'anarchie psychique affective et mentale, c'est le jeu des fonctions livrées à elles-mêmes et s'exerçant sans contrôle et sans but; dans le rêve l'esprit est un automate spirituel.' ²

Even Volkelt (1875, 14), whose theory is far from regarding psychical activity during sleep as purposeless, speaks of 'the relaxing, disconnecting and confusing of ideational life, which in the waking state is held together by the logical force of the central ego.'

The *absurdity* of the associations of ideas that occur in dreams could scarcely be criticized more sharply than it was by Cicero (*De divinatione*, II): 'Nihil tam praepostere, tam in condite, tam monstruose cogitari potest, quod non possimus somniare.' ³

Fechner (1889, 2, 522) writes: 'It is as though psychological activity had been transported from the brain of a reasonable man into that of a fool.'

¹ ['There are no dreams that are *absolutely* reasonable and that do not contain *some* incoherence, anachronism or absurdity.']

² ['A dream is psychical, emotional and mental anarchy; it is the play of functions left to their own devices and acting without control or purpose; in dreams the spirit becomes a spiritual automaton.']

³ ['There is no imaginable thing too absurd, too involved, or too abnormal for us to dream about it.']

Radestock (1879, 145): 'In fact it seems impossible to detect any fixed laws in this crazy activity. After withdrawing from the strict policing exercised over the course of waking ideas by the rational will and the attention, dreams melt into a mad whirl of kaleidoscopic confusion.'

Hildebrandt (1875, 45): 'What astonishing leaps a dreamer may make, for instance, in drawing inferences! How calmly he is prepared to see the most familiar lessons of experience turned upside down. What laughable contradictions he is ready to accept in the laws of nature and society before, as we say, things get beyond a joke and the excessive strain of nonsense wakes him up. We calculate without a qualm that three times three make twenty; we are not in the least surprised when a dog quotes a line of poetry, or when a dead man walks to his grave on his own legs, or when we see a rock floating on the water; we proceed gravely on an important mission to the Duchy of Bernburg or to the Principality of Liechtenstein to inspect their naval forces; or we are persuaded to enlist under Charles XII shortly before the battle of Poltava.'

Binz (1878, 33), having in mind the theory of dreams which is based upon such impressions as these, writes: 'The content of at least nine out of ten dreams is nonsensical. We bring together in them people and things that have no connection whatever with one another. Next moment there is a shift in the kaleidoscope and we are faced by a new grouping, more senseless and crazy, if possible, than the last. And so the changing play of the incompletely sleeping brain goes on, till we awake and clasp our forehead and wonder whether we still possess the capacity for rational ideas and thoughts.'

Maury (1878, 50) finds a parallel to the relation between dream-images and waking thoughts which will be highly significant to physicians: 'La production de ces images que chez l'homme éveillé fait le plus souvent naître la volonté, correspond, pour l'intelligence, à ce que sont pour la motilité certains mouvements que nous offre la choréé et les affections paralytiques. . .' He further regards dreams as 'toute une série de dégradations de la faculté pensante et raisonnante.' (Ibid., 27.)

It is scarcely necessary to quote the writers who repeat Maury's opinion in relation to the various higher mental functions. Strümpell (1877, 26), for instance, remarks that in dreams - even, of course, where there is no manifest nonsense - there is an eclipse of all the logical operations of the mind which are based on relations and connections. Spitta (1882, 148) declares that ideas that occur in dreams seem to be completely withdrawn from the law of causality. Radestock (1879,) and other writers insist upon the weakness of judgement and inference characteristic of dreams. According to Jodl (1896, 123), there is no critical faculty in dreams, no power of correcting one set of perceptions by reference to the general content of consciousness. The same author remarks that 'every kind of conscious activity occurs in dreams, but only in an incomplete, inhibited and isolated fashion.' The contradictions with our waking knowledge in which dreams are involved are explained by Stricker (1879, 98) and many others as being due to facts being forgotten in dreams or to logical relations between ideas having disappeared. And so on, and so on.

Nevertheless, the writers who in general take so unfavourable a view of psychical functioning in dreams allow that a certain remnant of mental activity still remains in them. This is explicitly admitted by Wundt, whose theories have had a determining influence on so many other workers in this field. What, it may be asked, is the nature of the remnant of normal mental activity which persists in dreams? There is fairly general agreement that the reproductive faculty, the memory, seems to have suffered least, and indeed that it shows a certain superiority to the same function in waking life (see Section B above), though some part of the absurdities of dreaming seems to be explicable by its forgetfulness. In the opinion of Spitta (1882, 84 f.) the part of the mind which is not affected by sleep is the life of the sentiments and it is this which directs dreams. By 'sentiment' [*Gemüt*] he means 'the stable assemblage of feelings which constitutes the innermost subjective essence of a human being'.

Scholz (1893, 64) believes that one of the mental activities operating in dreams is a tendency to subject the dream material to 're-interpretation in allegorical terms'. Siebeck too (1877, 11) sees in dreams a faculty of the mind for 'wider interpretation', which is exercised upon all sensations and perceptions. There is particular difficulty in assessing the position in dreams of what is ostensibly the highest of the psychical functions, that of consciousness. Since all that we know of dreams is derived from consciousness, there can be no doubt of its persisting in them; yet Spitta (1882, 84-5) believes that what persists in dreams is only consciousness and not *self*-consciousness. Delboeuf (1885, 19), however, confesses that he is unable to follow the distinction.

The laws of association governing the sequence of ideas hold good of dream-images, and indeed their dominance is even more clearly and strongly expressed in dreams. 'Dreams', says Strümpell (1877, 70), 'run their course, as it seems, according to the laws either of bare ideas or of organic stimuli accompanying such ideas - that is, without being in any way affected by reflection or common-sense or aesthetic taste or moral judgement.'

The authors whose views I am now giving picture the process of forming dreams in some such way as this. The totality of the sensory stimuli generated during sleep from the various sources which I have already enumerated arouse in the mind in the first place a number of ideas, which are represented in the form of hallucinations or more properly, according to Wundt, of illusions, in view of their derivation from external and internal stimuli. These ideas become linked together according to the familiar laws of association and, according to the same laws, call up a further series of ideas (or images). The whole of this material is then worked over, so far as it will allow, by what still remain in operation of the organizing and thinking faculties of the mind. (See, for instance, Wundt and Weygandt.) All that remain undiscovered are the motives which decide whether the calling up of images arising from non-external sources shall proceed along one chain of associations or another.

It has often been remarked, however, that the associations connecting dream-images with one another are of a quite special kind and differ from those which operate in waking thought. Thus Volkelt (1875, 15) writes: 'In dreams the associations seem to play at catch-as-catch-can in accordance with chance similarities and connections that are barely perceptible. Every dream is stuffed full of slovenly and perfunctory associations of this kind.' Maury (1878, 126) attaches very great importance to this feature of the way in which ideas are linked in dreams, since it enables him to draw a close analogy between dream-life and certain mental disorders. He specifies two main features of a '*délire*': '(1) une action spontanée et comme automatique de l'esprit; (2) une association vicieuse et irrégulière des idées.' ¹ Maury himself gives two excellent instances of dreams of his own in which dream-images were linked together merely through a similarity in the sound of words. He once dreamt that he was on a pilgrimage (*pélerinage*) to Jerusalem or Mecca; after many adventures he found himself visiting *Pelletier*, the chemist, who, after some conversation, gave him a zinc shovel (*pelle*); in the next part of the dream this turned into a great broadsword. (Ibid., 137.) In another dream he was walking along a highway and reading the number of *kilometres* on the milestones; then he was in a grocer's shop where there was a big pair of scales, and a man was putting *kilogramme* weights into the scale in order to weigh Maury; the grocer then said to him: 'You're not in Paris but on the island of *Gilolo*.' Several other scenes followed, in which he saw a *Lobelia* flower, and then General *Lopez*, of whose death he had read shortly before. Finally, while he was playing a game of *lotto*, he woke up. (Ibid., 126.)²

We shall no doubt be prepared to find, however, that this low estimate of psychical functioning in dreams has not been allowed to pass without contradiction - though contradiction on this point would seem to be no easy matter. For instance, Spitta (1882, 118), one of the disparagers of dream-life, insists that the same psychological laws which regulate waking life also hold good in dreams; and another, Dugas (1897a), declares that 'le rêve n'est pas déraison ni même irraison pure'.³ But such assertions carry little weight so long as their authors make no attempt to reconcile them with their own descriptions of the psychical anarchy and disruption of every function that prevail in dreams. It seems, however, to have dawned upon some other writers that the madness of dreams may not be without method and may even be simulated, like that of the Danish prince on whom this shrewd judgement was passed. These latter writers cannot have judged by appearances; or the appearance presented to them by dreams must have been a different one.

¹ ['(1) A mental act which is spontaneous and as it were automatic; (2) an invalid and irregular association of ideas.']

² [Footnote added 1909:] At later stage we shall come to understand the meaning of dreams such as this which are filled with alliterations and similar-sounding first syllables.

³ ['Dreams are not contrary to reason or even entirely lacking in reason.']

Thus Havelock Ellis (1899, 721), without dwelling on the apparent absurdity of dreams, speaks of them as 'an archaic world of vast emotions and imperfect thoughts', the study of which might reveal to us primitive stages in the evolution of mental life.

The same view is expressed by James Sully (1893, 362) in a manner that is both more sweeping and more penetrating. His words deserve all the more attention when we bear in mind that he was more firmly convinced, perhaps, than any other psychologist that dreams have a disguised meaning. 'Now our dreams are a means of conserving these successive personalities. *When asleep we go back to the old ways of looking at things and of feeling about them, to impulses and activities which long ago dominated us.*'

The sagacious Delboeuf (1885, 222) declares (though he puts himself in the wrong by not giving any refutation of the material which contradicts his thesis): 'Dans le sommeil, hormis la perception, toutes les facultés de l'esprit, intelligence, imagination, mémoire, volonté, moralité, restent intactes dans leur essence; seulement elles s'appliquent à des objets imaginaires et mobiles. Le songeur est un acteur qui joue à volonté les fous et les sages, les bourreaux et les victimes, les nains et les géants, les démons et les anges.' ¹

¹ ['In sleep, all the mental faculties (except for perception) - intelligence, imagination, memory, will and morality - remain essentially intact; they are merely applied to imaginary and unstable objects. A dreamer is an actor who at his own will plays the parts of madmen and philosophers, of executioners and their victims, of dwarfs and giants, of demons and angels.']

The most energetic opponent of those who seek to depreciate psychical functioning in dreams seems to be the Marquis d'Hervey de Saint-Denys, with whom Maury carried on a lively controversy, and whose book, in spite of all my efforts, I have not succeeded in procuring. Maury (1878, 19) writes of him: 'M. le Marquis d'Hervey prête à l'intelligence durant le sommeil, toute sa liberté d'action et d'attention et il ne semble faire consister le sommeil que dans l'occlusion des sens, dans leur fermeture au monde extérieur; en sorte que l'homme qui dort ne se distingue guère, selon sa manière de voir, de l'homme qui laisse vaguer sa pensée en se bouchant les sens; toute la différence qui sépare alors la pensée ordinaire de celle du dormeur c'est que, chez celui-ci, l'idée prend une forme visible, objective et ressemble, à s'y méprendre, à la sensation déterminée par les objets extérieurs; le souvenir revêt l'apparence du fait présent.' ¹ To this Maury adds 'qu'il y a une différence de plus et capitale à savoir que les facultés intellectuelles de l'homme endormi n'offrent pas l'équilibre qu'elles gardent chez l'homme éveillé.' ²

Vaschide (1911, 146 f.) gives us a clearer account of Hervey de Saint-Denys' book and quotes a passage from it upon the apparent incoherence of dreams: 'L'image du rêve est la copie de l'idée. Le principal est l'idée; la vision n'est qu'accessoire. Ceci établi, il faut savoir suivre la marche des idées, il faut savoir analyser le tissu des rêves; l'incohérence devient alors compréhensible, les conceptions les plus fantasques deviennent des faits simples et parfaitement logiques. . . . Les rêves les plus bizarres trouvent même une explication des plus logiques quand on sait les analyser.' ³

¹ ['The Marquis d'Hervey attributes complete liberty of action and attention to the intelligence during sleep, and he seems to think that sleep consists merely in the blocking of the senses, in their being closed to the external world. So that on his view a sleeping man would hardly be different from a man who shut off his senses and allowed his thought to wander; the only distinction between ordinary thoughts and those of a sleeper would be that, in the latter, ideas assume a visible and objective shape and are indistinguishable from sensations determined by external objects, while memories take on the appearance of present events.']

² ['There is a further distinction and one of capital importance: namely, that the intellectual faculties of a sleeping man do not exhibit the balance maintained in a man who is awake.']

³ ['Dream-images are copies of ideas. The essential thing is the idea, the vision is a mere accessory. When this is once established, we must know how to follow the sequence of the ideas, we must know how to analyse the texture of dreams; their incoherence then becomes intelligible, and the most fantastic notions become simple and perfectly logical facts. . . . We can even find a most logical explanation for the strangest dreams if we know how to analyse them.']

Johan Stårcke (1913, 243) has pointed out that a similar explanation of the incoherence of dreams was put forward by an earlier writer, Wolf Davidson (1799, 136), whose work was unknown to me: 'The remarkable leaps taken by our ideas in dreams all have their basis in the law of association; sometimes, however, these connections occur in the mind very obscurely, so that our ideas often seem to have taken a leap when in fact there has been none.'

The literature of the subject thus shows a very wide range of variation in the value which it assigns to dreams as psychical products. This range extends from the deepest disparagement, of the kind with which we have become familiar, through hints at a yet undisclosed worth, to an overvaluation which ranks dreams far higher than any of the functions of waking life. Hildebrandt (1875, 19 f.), who, as we have heard, has summed up the whole of the psychological features of dream-life in three antinomies, makes use of the two extreme ends of this range of values for his third paradox: 'it is a contrast between an intensification of mental life, an enhancement of it that not infrequently amounts to virtuosity, and, on the other hand, a deterioration and enfeeblement which often sinks below the level of humanity. As regards the former, there are few of us who could not affirm, from our own experience, that there emerges from time to time in the creations and fabrics of the genius of dreams a depth and intimacy of emotion, a tenderness of feeling, a clarity of vision, a subtlety of observation, and a brilliance of wit such as we should never claim to have at our permanent command in our waking lives. There lies in dreams a marvellous poetry, an apt allegory, an incomparable humour, a rare irony. A dream looks upon the world in a light of strange idealism and often enhances the effects of what it sees by its deep understanding of their essential nature. It pictures earthly beauty to our eyes in a truly heavenly splendour and clothes dignity with the highest majesty, it shows us our everyday fears in the ghastliest shape and turns our amusement into jokes of indescribable pungency. And sometimes, when we are awake and still under the full impact of an experience like one of these, we cannot but feel that never in our life has the real world offered us its equal.'

We may well ask whether the disparaging remarks quoted on earlier pages and this enthusiastic eulogy can possibly relate to the same thing. Is it that some of our authorities have overlooked the nonsensical dreams and others the profound and subtle ones? And if dreams of both kinds occur, dreams that justify both estimates, may it not be a waste of time to look for any distinguishing psychological feature of dreams? Will it not be enough to say that in dreams *anything* is possible - from the deepest degradation of mental life to an exaltation of it which is rare in waking hours? However convenient a solution of this kind might be, what lies against it is the fact that all of the efforts at research into the problem of dreams seem to be based on a conviction that some distinguishing feature *does* exist, which is universally valid in its essential outline and which would clear these apparent contradictions out of the way.

There can be no doubt that the psychical achievements of dreams received readier and warmer recognition during the intellectual period which has now been left behind, when the human mind was dominated by philosophy and not by the exact natural sciences. Pronouncements such as that by Schubert (1814, 20 f.) that dreams are a liberation of the spirit from the power of external nature, a freeing of the soul from the bonds of the senses, and similar remarks by the younger Fichte (1864, 1, 143 f.)¹ and others, all of which represent dreams as an elevation of mental life to a higher level, seem to us now to be scarcely intelligible; today they are repeated only by mystics and pietists.² The introduction of the scientific mode of thought has brought along with it a reaction in the estimation of dreams. Medical writers in especial tend to regard psychical activity in dreams as trivial and valueless; while philosophers and non-professional observers - amateur psychologists - whose contributions to this particular subject are not to be despised, have (in closer alignment with popular feeling) retained a belief in the psychical value of dreams. Anyone who is inclined to take a low view of psychical functioning in dreams will naturally prefer to assign their source to somatic stimulation; whereas those who believe that the dreaming mind retains the greater part of its waking capacities have of course no reason for denying that the stimulus to dreaming can arise within the dreaming mind itself.

¹ Cf. Haffner (1887) and Spitta (1882, 11 f.).

² [Footnote added 1914:] That brilliant mystic Du Prel, one of the few authors for whose neglect in earlier editions of this book I should wish to express my regret, declares that the gateway to metaphysics, so far as men are concerned, lies not in waking life but in the dream. (Du Prel, 1885, 59.)

Of the superior faculties which even a sober comparison may be inclined to attribute to dream-life, the most marked is that of memory; we have already discussed at length the not uncommon evidence in favour of this view. Another point of superiority in dream-life, often praised by earlier writers - that it rises superior to distance in time and space - may easily be shown to have no basis in fact. As Hildebrandt (1875,) points out, this advantage is an illusory one; for dreaming rises superior to time and space in precisely the same way as does waking thought, and for the very reason that it is merely a form of thought. It has been claimed for dreams that they enjoy yet another advantage over waking life in relation to time - that they are independent of the passage of time in yet another respect. Dreams such as the one dreamt by Maury of his own guillotining (see above, p. 539 f.) seem to show that a dream is able to compress into a very short space of time an amount of perceptual matter far greater than the amount of ideational matter that can be dealt with by our waking mind. This conclusion has however been countered by various arguments; since the papers by Le Lorrain (1894) and Egger (1895) on the apparent duration of dreams, a long and interesting discussion on the subject has developed, but it seems unlikely that the last word has yet been said on this subtle question and the deep implications which it involves.¹

Reports of numerous cases seem to put it beyond dispute that dreams can carry on the intellectual work of daytime and bring it to conclusions which had not been reached during the day, and that they can resolve doubts and problems and be the source of new inspiration for poets and musical composers. But though the *fact* may be beyond dispute, its implications are open to many doubts, which raise matters of principle.²

Lastly, dreams are reputed to have the power of divining the future. Here we have a conflict in which almost insuperable scepticism is met by obstinately repeated assertions. No doubt we shall be acting rightly in not insisting that this view has no basis at all in fact, since it is possible that before long a number of the instances cited may find an explanation within the bounds of natural psychology.

¹ [Footnote added 1914:] A further bibliography and a critical discussion of these problems will be found in Tobowolska (1900).

² [Footnote added 1914:] Cf. the criticism in Havelock Ellis (1911, 265).

(F)

THE MORAL SENSE IN DREAMS

For reasons which will only become apparent after my own investigations into dreams have been taken into account, I have isolated from the subject of the psychology of dreams the special problem of whether and to what extent moral dispositions and feelings extend into dream-life. Here too we are met by the same contradictory views which, curiously enough, we have found adopted by different authors in regard to all the other functions of the mind during dreams. Some assert that the dictates of morality have no place in dreams, while others maintain no less positively that the moral character of man persists in his dream-life.

Appeal to the common experience of dreams seems to establish beyond any doubt the correctness of the former of these views. Jessen (1855, 553) writes: 'Nor do we become better or more virtuous in sleep. On the contrary, conscience seems to be silent in dreams, for we feel no pity in them and may commit the worst crimes - theft, violence and murder - with complete indifference and with no subsequent feelings of remorse.'

Radestock (1879, 164): 'It should be borne in mind that associations occur and ideas are linked together in dreams without any regard for reflection, common sense, aesthetic taste or moral judgement. Judgement is extremely weak and ethical indifference reigns supreme.'

Volkelt (1875, 23): 'In dreams, as we are all aware, proceedings are especially unbridled in sexual matters. The dreamer himself is utterly shameless and devoid of any moral feeling or judgement; moreover, he sees everyone else, including those for whom he has the deepest respect, engaged in acts with which he would be horrified to associate them while he was awake, even in his thoughts.'

In diametrical opposition to these, we find statements such as Schopenhauer's that everyone who figures in a dream acts and speaks in complete accordance with his character. K. P. Fischer (1850, 72 f.), quoted by Spitta (1882, 188), declares that subjective feelings and longings, or affects and passions, reveal themselves in the freedom of dream-life, and that people's moral characteristics are reflected in their dreams.

Haffner (1884, 251): 'With rare exceptions . . . a virtuous man will be virtuous in his dreams as well; he will resist temptations and will keep himself aloof from hatred, envy, anger and all other vices. But a sinful man will as a rule find in his dreams the same images that he had before his eyes while he was awake.'

Scholz: 'In dreams is truth: in dreams we learn to know ourselves as we are in spite of all the disguises we wear to the world, The honourable man cannot commit a crime in dreams, or if he does he is horrified over it as over something contrary to his nature. The Roman Emperor who put a man to death who had dreamt that he had assassinated the ruler, was justified in so doing if he reasoned that the thoughts one has in dreams, one has, too, when awake. The common expression "I wouldn't dream of such a thing" has a doubly correct significance when it refers to something which can have no lodgement in our hearts or mind.' (Plato, on the contrary, thought that the best men are those who only *dream* what other men *do* in their waking life.)

Pfaff (1868), quoted by Spitta (1882, 192), alters the wording of a familiar saying: 'Tell me some of your dreams, and I will tell you about your inner self.'

The problem of morality in dreams is taken as the centre of interest by Hildebrandt, from whose small volume I have already quoted so much - for, of all the contributions to the study of dreams which I have come across, it is the most perfect in form and the richest in ideas. Hildebrandt too lays it down as a rule that the purer the life the purer the dream, and the more impure the one the more impure the other. He believes that man's moral nature persists in dreams. 'Whereas', he writes, 'even the grossest mistake in arithmetic, even the most romantic reversal of scientific laws, even the most ridiculous anachronism fails to upset us or even to arouse our suspicions, yet we never lose sight of the distinction between good and evil, between right and wrong or between virtue and vice. However much of what accompanies us in the daytime may drop away in our sleeping hours, Kant's categorical imperative is a companion who follows so close at our heels that we cannot be free of it even in sleep. . . . But this can only be explained by the fact that what is fundamental in man's nature, his moral being, is too firmly fixed to be affected by the kaleidoscopic shuffling to which the imagination, the reason, the memory and other such faculties must submit in dreams.' (Ibid., 45 f.)

As the discussion of this subject proceeds, however, both groups of writers begin to exhibit remarkable shifts and inconsistencies in their opinions. Those who maintain that the moral personality of man ceases to operate in dreams should, in strict logic, lose all interest in immoral dreams. They could rule out any attempt at holding a dreamer responsible for his dreams, or at deducing from the wickedness of his dreams that he had an evil streak in his character, just as confidently as they would reject a similar attempt at deducing from the absurdity of his dreams that his intellectual activities in waking life were worthless. The other group, who believe that the 'categorical imperative' extends to dreams, should logically accept unqualified responsibility for immoral dreams. We could only hope for their sake that they would have no such reprehensible dreams of their own to upset their firm belief in their own moral character.

It appears, however, that no one is as confident as all that of how far he is good or bad, and that no one can deny the recollection of immoral dreams of his own. For writers in both groups, irrespective of the opposition between their opinions on dream-morality, make efforts at explaining the origin of immoral dreams; and a fresh difference of opinion develops, according as their origin is sought in the functions of the mind or in deleterious effects produced on the mind by somatic causes. Thus the compelling logic of facts forces the supporters of both the responsibility and the irresponsibility of dream-life to unite in recognizing that the immorality of dreams has a specific psychical source.

Those who believe that morality extends to dreams are, however, all careful to avoid assuming *complete* responsibility for their dreams. Thus Haffner (1887, 250) writes: 'We are not responsible for our dreams, since our thought and will have been deprived in them of the basis upon which alone our life possesses truth and reality . . . For that reason no dream-wishes or dream-actions can be virtuous or sinful.' Nevertheless, he goes on, men are responsible for their sinful dreams in so far as they cause them indirectly. They have the duty of morally cleansing their minds not only in their waking life but more especially before going to sleep.

Hildebrandt presents us with a far deeper analysis of this mingled rejection and acceptance of responsibility for the moral content of dreams. He argues that in considering the immoral appearance of dreams allowance must be made for the dramatic form in which they are couched, for their compression of the most complicated processes of reflection into the briefest periods of time, as well as for the way in which, as even he admits, the ideational elements of dreams become confused and deprived of their significance. He confesses that he has the greatest hesitation, nevertheless, in thinking that all responsibility for sins and faults in dreams can be repudiated.

'When we are anxious to disown some unjust accusation, especially one that relates to our aims and intentions, we often use the phrase "I should never dream of such a thing", we are in that way expressing, on the one hand, our feeling that the region of dreams is the most remote and furthest in which we are answerable for our thoughts, since thoughts in that region are so loosely connected with our essential self that they are scarcely to be regarded as ours; but nevertheless, since we feel obliged expressly to deny the existence of these thoughts in this region, we are at the same time admitting indirectly that our self-justification would not be complete unless it extended so far. And I think that in this we are speaking, although unconsciously, the language of truth.' (Ibid., 49.)

'It is impossible to think of any action in a dream for which the original motive has not in some way or other - whether as a wish, or desire or impulse - passed through the waking mind.' We must admit, Hildebrandt proceeds, that this original impulse was not invented by the dream; the dream merely copied it and spun it out, it merely elaborated in dramatic form a scrap of historical material which it had found in us; it merely dramatized the Apostle's words: 'Whosoever hateth his brother is a murderer'. And although after we have awoken, conscious of our moral strength, we may smile at the whole elaborate structure of the sinful dream, yet the original material from which the structure was derived will fail to raise a smile. We feel responsible for the dreamer's errors - not for the whole amount of them, but for a certain percentage. 'In short, if we understand in this scarcely disputable sense Christ's saying that "out of the heart proceed evil thoughts", we can hardly escape the conviction that a sin committed in a dream bears with it at least an obscure minimum of guilt.' (Hildebrandt, 1875, 51 ff.)

Thus Hildebrandt finds the source of immorality in dreams in the germs and hints of evil impulses which, in the form of temptations, pass through our minds during the day; and he does not hesitate to include these immoral elements in his estimate of a person's moral value. These same thoughts, as we know, and this same estimate of them, are what have led the pious and saintly in every age to confess themselves miserable sinners.¹

There can of course be no doubt as to the general existence of such incompatible ideas; they occur in most people and in spheres other than that of ethics. Sometimes, however, they have been judged less seriously. Spitta (1882, 194) quotes some remarks by Zeller, which are relevant in this connection: 'A mind is seldom so happily organized as to possess complete power at every moment and not to have the regular and clear course of its thoughts constantly interrupted not only by inessential but by positively grotesque and nonsensical ideas. Indeed, the greatest thinkers have had to complain of this dreamlike, teasing and tormenting rabble of ideas, which have disturbed their deepest reflections and their most solemn and earnest thoughts.'

A more revealing light is thrown upon the psychological position of these incompatible thoughts by another remark of Hildebrandt's (1875, 55), to the effect that dreams give us an occasional glimpse into depths and recesses of our nature to which we usually have no access in our waking state. Kant expresses the same idea in a passage in his *Anthropologie* in which he declares that dreams seem to exist in order to show us our hidden natures and to reveal to us, not what we are, but what we might have been if we had been brought up differently. Radestock (1879, 84), too, says that dreams often do no more than reveal to us what we would not admit to ourselves and that it is therefore unfair of us to stigmatize them as liars and deceivers. Erdmann writes: 'Dreams have never shown me what I ought to think of a man; but I have occasionally learnt from a dream, greatly to my own astonishment, what I *do* think of a man and how I feel towards him.' Similarly I. H. Fichte (1864, I, 539) remarks: 'The nature of our dreams gives a far more truthful reflection of our whole disposition than we are able to learn of it from self-observation in waking life.'

¹ [Footnote added 1914:] It is of some interest to learn the attitude of the Inquisition to our problem. In Caesar Carena's *Tractatus de Officio sanctissimae Inquisitionis*, 1659, the following passage occurs: 'If anyone speaks heresies in a dream, the inquisitors should take occasion to enquire into his way of life, for what occupies a man during the day is wont to come again in his sleep.' (Communicated by Dr. Ehniger, St. Urban, Switzerland.)

It will be seen that the emergence of impulses which are foreign to our moral consciousness is merely analogous to what we have already learnt - the fact that dreams have access to ideational material which is absent in our waking state or plays but a small part in it. Thus Benini (1898) writes: ' Certe nostre inclinazioni che si credevano soffocate e spente da un pezzo, si ridestano; passioni vecchie e sepolte rivivono; cose e persone a cui non pensiamo mai, ci vengono dinanzi.' ¹ And Volkelt (1875, 105): 'Ideas, too, which have entered waking consciousness almost unnoticed and have perhaps never again been called to memory, very frequently announce their presence in the mind through dreams.' At this point, finally, we may recall Schleiermacher's assertion that the act of falling asleep is accompanied by the appearance of 'involuntary ideas' or images.

We may, then, class together under the heading of 'involuntary ideas' the whole of the ideational material the emergence of which, alike in immoral and in absurd dreams, causes us so much bewilderment. There is, however, one important point of difference: involuntary ideas in the moral sphere contradict our usual attitude of mind, whereas the others merely strike us as strange. No step has yet been taken towards a deeper knowledge which would resolve this distinction.

¹ ['Certain of our desires which have seemed for a time to be stifled and extinguished are re-awakened; old and buried passions come to life again; things and persons of whom we never think appear before us.']

The question next arises as to the *significance* of the appearance of involuntary ideas in dreams, as to the light which the emergence during the night of these morally incompatible impulses throws upon the psychology of the waking and dreaming mind. And here we find a fresh division of opinion and yet another different grouping of the authorities. The line of thought adopted by Hildebrandt and others who share his fundamental position inevitably leads to the view that immoral impulses possess a certain degree of power even in waking life, though it is an inhibited power, unable to force its way into action, and that in sleep something is put out of action which acts like an inhibition in the daytime and has prevented us from being aware of the existence of such impulses. Thus dreams would reveal the true nature of man, though not his *whole* nature, and they would constitute one means of rendering the hidden interior of the mind accessible to our knowledge. Only upon some such premises as these can Hildebrandt base his attribution to dreams of warning powers, which draw our attention to moral infirmities in our mind, just as physicians admit that dreams can bring unobserved physical illnesses to our conscious notice. So, too, Spitta must be adopting this view when, in speaking of the sources of excitation which impinge upon the mind (at puberty, for instance), he consoles the dreamer with the assurance that he will have done all that lies within his power if he leads a strictly virtuous life in his waking hours, and if he takes care to suppress sinful thoughts whenever they arise and to prevent their maturing and turning into acts. According to this view we might define the 'involuntary ideas' as ideas which had been 'suppressed' during the day, and we should have to regard their emergence as a genuine mental phenomenon.

Other writers, however, regard this last conclusion as unjustifiable. Thus Jessen (1855) believes that involuntary ideas, both in dreams and in waking, and in feverish and other delirious conditions, 'have the character of a volitional activity that has been put to rest and of a more or less mechanical succession of images and ideas provoked by internal impulses'. All that an immoral dream proves as to the dreamer's mental life is, in Jessen's view, that on some occasion he had cognizance of the ideational content in question; it is certainly no evidence of a mental impulse of the dreamer's own.

As regards another writer, Maury, it would almost seem as though he too attributes to the dreaming condition a capacity, not for the arbitrary destruction of mental activity, but for analysing it into its components. He writes as follows of dreams which transgress the bounds of morality: 'Ce sont nos penchants qui parlent et qui nous font agir, sans que la conscience nous retienne, bien que parfois elle nous avertisse. J'ai mes défauts et mes penchants vicieux; à l'état de veille je tâche de lutter contre eux, et il m'arrive assez souvent de n'y pas succomber. Mais dans mes songes j'y succombe toujours ou pour mieux dire j'agis par leur impulsion, sans crainte et sans remords. . . . Evidemment les visions qui se déroulent devant ma pensée et qui constituent le rêve, me sont suggérées par les incitations que je ressens et que ma volonté absente ne cherche pas à refouler.' (Maury, 1878, 113.)¹

No one who believes in the capacity of dreams to reveal an immoral tendency of the dreamer's which is really present though suppressed or concealed, could express his view more precisely than in Maury's words: 'En rêve l'homme se révèle donc tout entier à soi-même dans sa nudité et sa misère natives. Dès qu'il suspend l'exercice de sa volonté, il devient le jouet de toutes les passions contre lesquelles, à l'état de veille, la conscience, le sentiment de l'honneur, la crainte nous défendent.' (Ibid., 165.)² In another passage we find these pertinent sentences: 'Dans le songe, c'est surtout l'homme instinctif qui se révèle. . . . L'homme revient pour ainsi dire à l'état de nature quand il rêve; mais moins les idées acquises ont pénétré dans son esprit, plus les penchants en désaccord avec elles conservent encore sur lui l'influence dans le rêve.' (Ibid., 462.)³ He goes on to relate by way of example how in his dreams he is not infrequently the victim of the very superstition which he has been attacking in his writings with particular vehemence.

¹ ['It is our impulses that are speaking and making us act, while our conscience does not hold us back, though it sometimes warns us. I have my faults and my vicious impulses; while I am awake I try to resist them, and quite often I succeed in not yielding to them. But in my dreams I *always* yield to them, or rather I act under their pressure without fear or remorse. . . . The visions which unroll before my mind and which constitute a dream are clearly suggested by the urges which I feel and which my absent will does not attempt to repress.']

² ['Thus in dreams a man stands self-revealed in all his native nakedness and poverty. As soon as he suspends the exercise of his will, he becomes the plaything of all the passions against which he is defended while he is awake by his conscience, his sense of honour and his fears.']

³ ['What is revealed in dreams is primarily the man of instinct. . . . Man may be said to return in his dreams to a state of nature. But the less his mind has been penetrated by acquired ideas, the more it remains influenced in dreams by impulses of a contrary nature.']

These penetrating reflections of Maury's, however, lose their value in the investigation of dream-life owing to the fact that he regards the phenomena which he has observed with such accuracy as no more than proofs of an '*automatisme psychologique*' which, in his view, dominates dreams and which he looks upon as the exact opposite of mental activity.

Stricker (1879) writes: 'Dreams do not consist solely of illusions. If, for instance, one is afraid of robbers in a dream, the robbers, it is true, are imaginary - but the fear is real.' This calls our attention to the fact that *affects* in dreams cannot be judged in the same way as the remainder of their content; and we are faced by the problem of what part of the psychical processes occurring in dreams is to be regarded as real, that is to say, has a claim to be classed among the psychical processes of waking life.

(G)

THEORIES OF DREAMING AND ITS FUNCTION

Any disquisition upon dreams which seeks to explain as many as possible of their observed characteristics from a particular point of view, and which at the same time defines the position occupied by dreams in a wider sphere of phenomena, deserves to be called a theory of dreams. The various theories will be found to differ in that they select one or the other characteristic of dreams as the essential one and take it as the point of departure for their explanations and correlations. It need not necessarily be possible to infer a *function* of dreaming (whether utilitarian or otherwise) from the theory. Nevertheless, since we have a habit of looking for teleological explanations, we shall be more ready to accept theories which are bound up with the attribution of a function to dreaming.

We have already made the acquaintance of several sets of views which deserve more or less to be called theories of dreams in this sense of the term. The belief held in antiquity that dreams were sent by the gods in order to guide the actions of men was a complete theory of dreams, giving information on everything worth knowing about them. Since dreams have become an object of scientific research a considerable number of theories have been developed, including some that are extremely incomplete.

Without attempting any exhaustive enumeration, we may try to divide theories of dreams into the following three rough groups, according to their underlying assumptions as to the amount and nature of psychical activity in dreams.

(1) There are the theories, such as that of Delboeuf, according to which the whole of psychical activity continues in dreams. The mind, they assume, does not sleep and its apparatus remains intact; but, since it falls under the conditions of the state of sleep, which differ from those of waking life, its normal functioning necessarily produces different results during sleep. The question arises in regard to these theories whether they are capable of deriving all the distinctions between dreams and waking thought from the conditions of the state of sleep. Moreover, there is no possibility of their being able to suggest any function for dreaming; they offer no reason why we should dream, why the complicated mechanism of the mental apparatus should continue to operate even when set in circumstances for which it appears undesigned. Either dreamless sleep or, if disturbing stimuli intervene, awakening, would seem to be the only expedient reactions - rather than the third alternative of dreaming.

(2) There are the theories which, on the contrary, presuppose that dreams imply a lowering of psychical activity, a loosening of connections, and an impoverishment of the material accessible. These theories must imply the attribution to sleep of characteristics quite different from those suggested, for instance, by Delboeuf. Sleep, according to such theories, has a far reaching influence upon the mind; it does not consist merely in the mind being shut off from the external world; it forces its way, rather, into the mental mechanism and throws it temporarily out of use. If I may venture on a simile from the sphere of psychiatry, the first group of theories construct dreams on the model of paranoia, while the second group make them resemble mental deficiency or confusional states.

The theory according to which only a fragment of mental activity finds expression in dreams, since it has been paralysed by sleep, is by far the most popular with medical writers and in the scientific world generally. In so far as any general interest may be supposed to exist in the explanation of dreams, this may be described as the ruling theory. It is to be remarked how easily this theory avoids the worst stumbling-block in the way of any explanation of dreams - the difficulty of dealing with the contradictions involved in them. It regards dreams as a result of a partial awakening - 'a gradual, partial and at the same time highly abnormal awakening', to quote a remark of Herbart's upon dreams (1892, 307). Thus, this theory can make use of a series of conditions of ever-increasing wakefulness, culminating in the completely waking state, in order to account for the series of variations in efficiency of mental functioning in dreams, ranging from the inefficiency revealed by their occasional absurdity up to fully concentrated intellectual functioning.

Those who find that they cannot dispense with a statement in terms of physiology, or to whom a statement in such terms seems more scientific, will find what they want in the account given by Binz (1878, 43): 'This condition' (of torpor) 'comes to an end in the early hours of the morning, but only by degrees. The products of fatigue which have accumulated in the albumen of the brain gradually diminish; more and more of them are decomposed or eliminated by the unceasing flow of the blood stream. Here and there separate groups of cells begin to emerge into wakefulness, while the torpid state still persists all around them. The isolated work of these separate groups now appears before our clouded consciousness, unchecked by other portions of the brain which govern the process of association. For that reason the images produced, which correspond for the most part to material impressions of the more recent past, are strung together in a wild and irregular manner. The number of the liberated brain-cells constantly grows and the senselessness of the dreams correspondingly diminishes.'

This view of dreaming as an incomplete, partial waking state is no doubt to be found in the writings of every modern physiologist and philosopher. The most elaborate exposition of it is given by Maury (1878, 6 f.). It often appears as though that author imagined that the waking or sleeping state could be shifted from one anatomical region to another, each particular anatomical region being linked to one particular psychical function. I will merely remark at this point that, even if the theory of partial waking were confirmed, its details would still remain very much open to discussion.

This view naturally leaves no room for assigning any function to dreaming. The logical conclusion that follows from it as to the position and significance of dreams is correctly stated by Binz (1878, 35): 'Every observed fact forces us to conclude that dreams must be characterized as *somatic* processes, which are in every case useless and in many cases positively pathological. . . .'

The application to dreams of the term 'somatic', which is italicized by Binz himself, has more than one bearing. It alludes, in the first place, to the *aetiology* of dreams which seemed particularly plausible to Binz when he studied the experimental production of dreams by the use of toxic substances. For theories of this kind involve a tendency to limit the instigation of dreams so far as possible to somatic causes. Put in its most extreme form the view is as follows. Once we have put ourselves to sleep by excluding all stimuli, there is no need and no occasion for dreaming until the morning, when the process of being gradually awakened by the impact of fresh stimuli might be reflected in the phenomenon of dreaming. It is impracticable, however, to keep our sleep free from stimuli; they impinge upon the sleeper from all sides - like the germs of life of which Mephistopheles complained - from without and from within and even from parts of his body which are quite unnoticed in waking life. Thus sleep is disturbed; first one corner of the mind is shaken into wakefulness and then another; the mind functions for a brief moment with its awakened portion and is then glad to fall asleep once more. Dreams are a reaction to the disturbance of sleep brought about by a stimulus - a reaction, incidentally, which is quite superfluous.

But the description of dreaming - which, after all is said and done, remains a function of the mind - as a somatic process implies another meaning as well. It is intended to show that dreams are unworthy to rank as psychical processes. Dreaming has often been compared with 'the ten fingers of a man who knows nothing of music wandering over the keys of a piano' ; and this simile shows as well as anything the sort of opinion that is usually held of dreaming by representatives of the exact sciences. On this view a dream is something wholly and completely incapable of interpretation; for how could the ten fingers of an unmusical player produce a piece of music?

Even in the distant past there was no lack of critics of the theory of partial waking. Thus Burdach (1838, 508 f.) wrote: 'When it is said that dreams are a partial waking, in the first place this throws no light either on waking or on sleeping, and in the second place it says no more than that some mental forces are active in dreams while others are at rest. But variability of this kind occurs throughout life.'

This ruling theory, which regards dreams as a somatic process, underlies a most interesting hypothesis put forward for the first time by Robert in 1886. It is particularly attractive since it is able to suggest a function, a utilitarian purpose, for dreaming. Robert takes as the groundwork of his theory two facts of observation which we have already considered in the course of our examination of the material of dreams (see above, p. 532 ff.), namely that we dream so frequently of the most trivial daily impressions and that we so rarely carry over into our dreams our important daily interests. Robert (1886, 10) asserts that it is universally true that things which we have thoroughly thought out never become instigators of dreams but only things which are in our minds in an uncompleted shape or which have merely been touched upon by our thoughts in passing: 'The reason why it is usually impossible to explain dreams is precisely because they are caused by sensory impressions of the preceding day which failed to attract enough of the dreamer's attention.' Thus the condition which determines whether an impression shall find its way into a dream is whether the process of working over the impression was interrupted or whether the impression was too unimportant to have a right to be worked over at all.

Robert describes dreams as 'a somatic process of excretion of which we become aware in our mental reaction to it'. Dreams are excretions of thought that have been stifled at birth. 'A man deprived of the capacity for dreaming would in course of time become mentally deranged, because a great mass of uncompleted, unworked-out thoughts and superficial impressions would accumulate in his brain and would be bound by their bulk to smother the thoughts which should be assimilated into his memory as completed wholes.' Dreams serve as a safety-valve for the over-burdened brain. They possess the power to heal and relieve. (Ibid., 32.)

We should be misunderstanding Robert if we were to ask him how it can come about that the mind is relieved through the presentation of ideas in dreams. What Robert is clearly doing is to infer from these two features of the material of dreams that by some means or other an expulsion of worthless impressions is accomplished during sleep as a somatic process, and that dreaming is not a special sort of psychical process but merely the information we receive of that expulsion. Moreover, excretion is not the only event which occurs in the mind at night. Robert himself adds that, besides this, the suggestions arising during the previous day are worked out and that 'whatever parts of the undigested thoughts are not excreted are bound together into a rounded whole by threads of thought borrowed from the imagination and thus inserted in the memory as a harmless imaginative picture.' (Ibid., 23.)

But Robert's theory is diametrically opposed to the ruling one in its estimate of the nature of the *sources* of dreams. According to the latter, there would be no dreaming at all if the mind were not being constantly wakened by external and internal sensory stimuli. But in Robert's view the impulsion to dreaming arises in the mind itself - in the fact of its becoming overloaded and requiring relief; and he concludes with perfect logic that causes derived from somatic conditions play a subordinate part as determinants of dreams, and that such causes would be quite incapable of provoking dreams in a mind in which there was no material for the construction of dreams derived from waking consciousness. The only qualification he makes is to admit that the phantasy-images arising in dreams out of the depths of the mind may be affected by nervous stimuli. (Ibid., 48.) After all, therefore, Robert does not regard dreams as so completely dependent upon somatic events. Nevertheless, in his view dreams are not psychical processes, they have no place among the psychical processes of waking life; they are somatic processes occurring every night in the apparatus that is concerned with mental activity, and they have as their function the task of protecting that apparatus from excessive tension - or, to change the metaphor - of acting as scavengers of the mind.

Another writer, Yves Delage, bases his theory on the same features of dreams, as revealed in the choice of their material; and it is instructive to notice the way in which a slight variation in his view of the same things leads him to conclusions of a very different bearing.

Delage (1891, 41) tells us that he experienced in his own person, on the occasion of the death of someone of whom he was fond, the fact that we do *not* dream of what has occupied all our thoughts during the day, or not until it has begun to give place to other daytime concerns. His investigations among other people confirmed him in the general truth of this fact. He makes what would be an interesting observation of this kind, if it should prove to have general validity, on the dreams of young married couples: 'S'ils ont été fortement épris, presque jamais ils n'ont rêvé l'un de l'autre avant le mariage ou pendant la lune de miel; et s'ils ont rêvé d'amour c'est pour être infidèles avec quelque personne indifférente ou odieuse.' What, then, do we dream of? Delage identifies the material that occurs in our dreams as consisting of fragments and residues of the preceding days and of earlier times. Everything that appears in our dreams, even though we are inclined at first to regard it as a creation of our dream-life, turns out, when we have examined it more closely, to be unrecognized reproduction - 'souvenir inconscient'. But this ideational material possesses a common characteristic: it originates from impressions which probably affected our senses more strongly than our intelligence or from which our attention was diverted very soon after they emerged. The less conscious and at the same time the more powerful an impression has been, the more chance it has of playing a part in the next dream.

Here we have what are essentially the same two categories of impressions as are stressed by Robert: the trivial ones and those that have not been dealt with. Delage, however, gives the situation a different turn, for he holds that it is because these impressions have not been dealt with that they are capable of producing dreams, not because they are trivial. It is true in a certain sense that trivial impressions, too, have not been dealt with completely; being in the nature of fresh impressions, they are 'autant de ressorts tendus' which are released during sleep. A powerful impression which happens to have met with some check in the process of being worked over or which has been purposely held under restraint has more claim to play a part in dreams than an impression which is weak and almost unnoticed. The psychical energy which has been stored up during the daytime by being inhibited and suppressed becomes the motive force for dreams at night. Psychical material that has been suppressed comes to light in dreams.¹

At this point, unluckily, Delage interrupts his train of thought. He can attribute only the smallest share in dreams to any independent psychical activity; and thus he brings his theory into line with the ruling theory of the partial awakening of the brain: 'En somme le rêve est le produit de la pensée errante, sans but et sans direction, se fixant successivement sur les souvenirs, qui ont gardé assez d'intensité pour se placer sur sa route et l'arrêter au passage, établissant entre eux un lien tantôt faible et indécis, tantôt plus fort et plus serré, selon que l'activité actuelle du cerveau est plus ou moins abolie par le sommeil.'²

¹ [Footnote added 1909:] Anatole France expresses exactly the same idea in *Le lys rouge*: 'Ce que nous voyons la nuit, ce sont les restes malheureux de ce que nous avons négligé dans la veille. Le rêve est souvent la revanche des choses qu'on méprise ou le reproche des êtres abandonnés.' ['What we see during the night are the miserable remnants of what we have neglected during the previous day. A dream is often a retaliation on the part of what we despise or a reproach on the part of those we have deserted.']

² ['In short, dreams are the product of thought wandering without purpose or direction, attaching itself in turn to memories which have retained enough intensity to stand in its way and interrupt its course, and linking them together by a bond which is sometimes weak and vague and sometimes stronger and closer, according as the brain's activity at the moment is abolished by sleep to a greater or less extent.']

(3) We may place in a third group those theories which ascribe to the dreaming mind a capacity and inclination for carrying out special psychical activities of which it is largely or totally incapable in waking life. The putting of these faculties into force usually provides dreaming with a utilitarian function. Most of the estimates formed of dreaming by earlier writers on psychology fall into this class. It will be enough, however, for me to quote a sentence from Burdach (1838, 512). Dreaming, he writes, 'is a natural activity of the mind which is not limited by the power of individuality, which is not interrupted by self-consciousness and which is not directed by self-determination, but which is the freely operating vitality of the sensory centres.'

This revelling of the mind in the free use of its own forces is evidently regarded by Burdach and the rest as a condition in which the mind is refreshed and collects new strength for the day's work - in which, in fact, it enjoys a sort of holiday. Thus Burdach quotes with approval the charming words in which the poet Novalis praises the reign of dreams: 'Dreams are a shield against the humdrum monotony of life; they set imagination free from its chains so that it may throw into confusion all the pictures of everyday existence and break into the unceasing gravity of grown men with the joyful play of a child. Without dreams we should surely grow sooner old; so we may look on them - not, perhaps as a gift from on high - but as a precious recreation, as friendly companions on our pilgrimage to the grave.'

The reviving and healing function of dreams is described with still more insistence by Purkinje (1846, 456): 'These functions are performed especially by productive dreams. They are the easy play of the imagination and have no connection with the affairs of daytime. The mind has no wish to prolong the tensions of waking life; it seeks to relax them and to recover from them. It produces above all conditions contrary to the waking ones. It cures sorrow by joy, cares by hopes and pictures of happy distraction, hatred by love and friendliness, fear by courage and foresight; it allays doubt by conviction and firm faith, and vain expectation by fulfilment. Many of the spirit's wounds which are being constantly re-opened during the day are healed by sleep, which covers them and shields them from fresh injury. The healing action of time is based partly on this.' We all have a feeling that sleep has a beneficial effect upon mental activities, and the obscure working of the popular mind refuses to let itself be robbed of its belief that dreaming is one of the ways in which sleep dispenses its benefits.

The most original and far-reaching attempt to explain dreaming as a special activity of the mind, capable of free expansion only during the state of sleep, was that undertaken by Scherner in 1861. His book is written in a turgid and high-flown style and is inspired by an almost intoxicated enthusiasm for his subject which is bound to repel anyone who cannot share in his fervour. It puts such difficulties in the way of an analysis of its contents that we turn with relief to the clearer and briefer exposition of Scherner's doctrines given by the philosopher Volkelt. 'Suggestive gleams of meaning proceed like lightning flashes out of these mystical agglomerations, these clouds of glory and splendour - but they do not illuminate a philosopher's path.' It is in these terms that Scherner's writings are judged even by his disciple.

Schermer is not one of those who believe that the capacities of the mind continue undiminished in dream-life. He himself shows how the centralized core of the ego - its spontaneous energy - is deprived of its nervous force in dreams, how as a result of this decentralization the processes of cognition, feeling, willing and ideation are modified, and how the remnants of these psychical functions no longer possess a truly mental character but become nothing more than mechanisms. But by way of contrast, the mental activity which may be described as 'imagination', liberated from the domination of reason and from any moderating control, leaps into a position of unlimited sovereignty. Though dream-imagination makes use of recent waking memories for its building material, it erects them into structures bearing not the remotest resemblance to those of waking life; it reveals itself in dreams as possessing not merely reproductive but *productive* powers. Its characteristics are what lend their peculiar features to dreams. It shows a preference for what is immoderate, exaggerated and monstrous. But at the same time, being freed from the hindrances of the categories of thought, it gains in pliancy, agility and versatility. It is susceptible in the subtlest manner to the shades of the tender feelings and to passionate emotions, and promptly incorporates our inner life into external plastic pictures. Imagination in dreams is without the power of conceptual speech. It is obliged to paint what it has to say pictorially, and, since there are no concepts to exercise an attenuating influence, it makes full and powerful use of the pictorial form. Thus, however clear its speech may be, it is diffuse, clumsy and awkward. The clarity of its speech suffers particularly from the fact that it has a dislike of representing an object by its proper image, and prefers some extraneous image which will express only that particular one of the object's attributes which it is seeking to represent. Here we have the 'symbolizing activity' of the imagination. . . . Another very important point is that dream-imagination never depicts things completely, but only in outline and even so only in the roughest fashion. For this reason its paintings seem like inspired sketches. It does not halt, however, at the mere representation of an object; it is under an internal necessity to involve the dream-ego to a greater or less extent with the object and thus produce an *event*. For instance, a dream caused by a visual stimulus may represent gold coins in the street; the dreamer will pick them up delightedly and carry them off.

The material with which dream-imagination accomplishes its artistic work is principally, according to Scherner, provided by the organic somatic stimuli which are so obscure during the daytime. (See above, p. 544 ff.) Thus the excessively fantastic hypothesis put forward by Scherner and the perhaps unduly sober doctrines of Wundt and other physiologists, which are poles asunder in other respects, are entirely at one in regard to their theory of the sources and instigators of dreams. According to the physiological view, however, the mental reaction to the internal somatic stimuli is exhausted with the provoking of certain ideas appropriate to the stimuli; these ideas give rise to others along associative lines and at this point the course of psychical events in dreams seems to be at an end. According to Scherner, on the other hand, the somatic stimuli do no more than provide the mind with material of which it can make use for its imaginative purposes. The formation of dreams only begins, in Scherner's eyes, at the point which the other writers regard as its end.

What dream-imagination does to the somatic stimuli cannot, of course, be regarded as serving any useful purpose. It plays about with them and pictures the organic sources, from which the stimuli of the dream in question have arisen, in some kind of plastic symbolism. Scherner is of the opinion - though here Volkelt and others refuse to follow him - that dream imagination has one particular favourite way of representing the organism as a whole: namely as a house. Fortunately, however, it does not seem to be restricted to this one method of representation. On the other hand, it may make use of a whole row of houses to indicate a single organ; for instance, a very long street of houses may represent a stimulus from the intestines. Again, separate portions of a house may stand for separate portions of the body; thus, in a dream caused by a headache, the head may be represented by the ceiling of a room covered with disgusting, toad-like spiders.

Leaving this house-symbolism on one side, any number of other kinds of things may be used to represent the parts of the body from which the stimulus to the dream has arisen. 'Thus the breathing lung will be symbolically represented by a blazing furnace, with flames roaring with a sound like the passage of air; the heart will be represented by hollow boxes or baskets, the bladder by round, bag-shaped objects or, more generally, by hollow ones. A dream caused by stimuli arising from the male sexual organs may cause the dreamer to find the top part of a clarinet in the street or the mouth-piece of a tobacco-pipe, or again, a piece of fur. Here the clarinet and the tobacco-pipe represent the approximate shape of the male organ, while the fur stands for the pubic hair. In the case of a sexual dream in a woman, the narrow space where the thighs come together may be represented by a narrow courtyard surrounded by houses, while the vagina may be symbolized by a soft, slippery and very narrow foot-path leading across the yard, along which the dreamer has to pass, in order, perhaps, to take a gentleman a letter.' (Ibid., 34.) It is of special importance that, at the end of dreams with a somatic stimulus, such as these, the dream imagination often throws aside its veil, as it were, by openly revealing the organ concerned or its function. Thus a dream 'with a dental stimulus' usually ends by the dreamer picturing himself pulling a tooth out of his mouth.

Dream-imagination may, however, not merely direct its attention to the *form* of the stimulating organ; it may equally well symbolize the substance contained in that organ. In this way, a dream with an intestinal stimulus may lead the dreamer along muddy streets, or one with a urinary stimulus may lead him to a foaming stream. Or the stimulus as such, the nature of the excitement it produces, or the object it desires, may be symbolically represented. Or the dream-ego may enter into concrete relations with the symbols of its own state; for instance, in the case of painful stimuli the dreamer may engage in a desperate struggle with fierce dogs or savage bulls, or a woman in a sexual dream may find herself pursued by a naked man. Quite apart from the wealth of the means that it employs, the symbolizing activity of the imagination remains the central force in every dream. The task of penetrating more deeply into the nature of this imagination and of finding a place for it in a system of philosophical thought is attempted by Volkelt in the pages of his book. But, though it is well and feelingly written, it remains excessively hard to understand for anyone whose early education has not prepared him for a sympathetic grasp of the conceptual constructions of philosophy.

There is no utilitarian function attached to Scherner's symbolizing imagination. The mind plays in its sleep with the stimuli that impinge upon it. One might almost suspect that it plays with them mischievously. But I might also be asked whether my detailed examination of Scherner's theory of dreams can serve any utilitarian purpose, since its arbitrary character and its disobedience to all the rules of research seem only too obvious. By way of rejoinder, I might register a protest against the arrogance which would dismiss Scherner's theory unexamined. His theory is built upon the impression made by his dreams upon a man who considered them with the greatest attention and seems to have had a great personal gift for investigating the obscure things of the mind. Moreover it deals with a subject that for thousands of years has been regarded by mankind as enigmatic, no doubt, but also as important in itself and its implications - a subject to the elucidation of which exact science, on its own admission, has contributed little apart from an attempt (in direct opposition to popular feeling) to deny it any meaning or significance. And finally it may honestly be said that in attempting to explain dreams it is not easy to avoid being fantastic. Ganglion cells can be fantastic too. The passage which I quoted on p. 584 from a sober and exact investigator like Binz, and which describes the way in which the dawn of awakening steals over the mass of sleeping cells in the cerebral cortex, is no less fantastic - and no less improbably - than Scherner's attempts at interpretation. I hope to be able to show that behind the latter there is an element of reality, though it has only been vaguely perceived and lacks the attribute of universality which should characterize a theory of dreams. Meanwhile the contrast between Scherner's theory and the medical one will show us the extremes between which explanations of dream-life doubtfully oscillate to this very day.

(H)

THE RELATIONS BETWEEN DREAMS AND MENTAL DISEASES

When we speak of the relation of dreams to mental disorders we may have three things in mind: (1) aetiological and clinical connections, as when a dream represents a psychotic state, or introduces it, or is left over from it; (2) modifications to which dream-life is subject in cases of mental disease; and (3) intrinsic connections between dreams and psychoses, analogies pointing to their being essentially akin. These numerous relations between the two groups of phenomena were a favourite topic among medical writers in earlier times and have become so once again to-day, as is shown by the bibliographies of the subject collected by Spitta, Radestock, Maury and Tissié. Quite recently Sante de Sanctis has turned his attention to this subject.¹ It will be enough for the purpose of my thesis if I do no more than touch upon this important question.

As regards the clinical and aetiological connections between dreams and psychoses, the following observations may be given as samples. Hohnbaum, quoted by Krauss, reports that a first outbreak of delusional insanity often originates in an anxious or terrifying dream, and that the dominant idea is connected with the dream. Sante de Sanctis brings forward similar observations in cases of paranoia and declares that in some of these the dream was the 'vraie cause déterminante de la folie'. The psychosis, says de Sanctis, may come to life at a single blow with the appearance of the operative dream which brings the delusional material to light; or it may develop slowly in a series of further dreams, which have still to overcome a certain amount of doubt. In one of his cases the significant dream was followed by mild hysterical attacks and later by a condition of anxious melancholia. Férée (quoted by Tissié, 1898) reports a dream which resulted in a hysterical paralysis. In these instances the dreams are represented as the aetiology of the mental disorder; but we should be doing equal justice to the facts if we said that the mental disorder made its first appearance in dream-life, that it first broke through in a dream. In some further examples the pathological symptoms are contained in dream-life, or the psychosis is limited to dream-life. Thus Thomayer (1897) draws attention to certain anxiety-dreams which he thinks should be regarded as equivalents of epileptic fits. Allison (quoted by Radestock, 1879) has described a 'nocturnal insanity', in which the patient appears completely healthy during the day but is regularly subject at night to hallucinations, fits of frenzy, etc. Similar observations are reported by de Sanctis (a dream of an alcoholic patient which was equivalent to a paranoia, and which represented voices accusing his wife of unfaithfulness) and Tissié. The latter (1898) gives copious recent examples in which acts of a pathological nature, such as conduct based on delusional premises and obsessive impulses, were derived from dreams. Guislain describes a case in which sleep was replaced by an intermittent insanity.

¹ [Footnote added 1914:] Among later writers who deal with these relations are Féré, Ideler, Lasègue, Pichon, Régis, Vespa, Giessler, Kazowsky, Pachantoni, etc.

There can be no doubt that alongside of the psychology of dreams physicians will some day have to turn their attention to a *psychopathology* of dreams.

In cases of recovery from mental diseases it can often be quite clearly observed that, while functioning is normal during the day, dream-life is still under the influence of the psychosis. According to Krauss (1859, 270), Gregory first drew attention to this fact. Macario, quoted by Tissié, describes how a manic patient, a week after his complete recovery was still subject in his dreams to the flight of ideas and the violent passions which were characteristic of his illness.

Very little research has hitherto been carried out into the modifications occurring in dream-life during chronic psychoses. On the other hand, attention was long ago directed to the underlying kinship between dreams and mental disorders, exhibited in the wide measure of agreement between their manifestations. Maury (1854, 124) tells us that Cabanis (1802) was the first to remark on them, and after him Lélut, J. Moreau (1855) and, in particular, Maine de Biran the philosopher. No doubt the comparison goes back still earlier. Radestock (1879, 217) introduces the chapter in which he deals with it by a number of quotations drawing an analogy between dreams and madness. Kant writes somewhere: 'The madman is a waking dreamer.' Krauss (1859, 270) declares that 'insanity is a dream dreamt while the senses are awake'. Schopenhauer calls dreams a brief madness and madness a long dream. Hagen describes delirium as dream-life induced not by sleep but by illness. Wundt writes: 'We ourselves, in fact, can experience in dreams almost all the phenomena to be met with in insane asylums.'

Spitta (1882, 199), in much the same way as Maury (1854), enumerates as follows the different points of agreement which constitute the basis for this comparison: '(1) Self-consciousness is suspended or at least retarded, which results in a lack of insight into the nature of the condition, with consequent inability to feel surprise and loss of moral consciousness. (2) Perception by the sense organs is modified: being diminished in dreams but as a rule greatly increased in insanity. (3) Interconnection of ideas occurs exclusively according to the laws of association and reproduction; ideas thus fall into sequences automatically and there is a consequent lack of proportion in the relation between ideas (exaggerations and illusions). All this leads to (4) an alteration or in some cases a reversal of personality and occasionally of character traits (perverse conduct).'

Radestock (1879, 219) adds a few more features - analogies between the *material* in the two cases: 'The majority of hallucinations and illusions occur in the region of the senses of sight and hearing and of coenaesthesia. As in the case of dreams, the senses of smell and taste provide the fewest elements. - Both in patients suffering from fever and in dreamers memories arise from the remote past; both sleeping and sick men recollect things which waking and healthy men seem to have forgotten.' The analogy between dreams and psychoses is only fully appreciated when it is seen to extend to the details of expressive movement and to particular characteristics of facial expression.

'A man tormented by physical and mental suffering obtains from dreams what reality denies him: health and happiness. So too in mental disease there are bright pictures of happiness, grandeur, eminence and wealth. The supposed possession of property and the imaginary fulfilment of wishes - the withholding or destruction of which actually affords a psychological basis for insanity - often constitute the chief content of a delirium. A woman who has lost a loved child experiences the joys of motherhood in her delirium; a man who has lost his money believes himself immensely rich; a girl who has been deceived feels that she is tenderly loved.'

(This passage from Radestock is actually a summary of an acute observation made by Griesinger (1861, 106), who shows quite clearly that ideas in dreams and in psychoses have in common the characteristic of being *fulfilments of wishes*. My own researches have taught me that in this fact lies the key to a psychological theory of both dreams and psychoses.)

'The chief feature of dreams and of insanity lies in their eccentric trains of thought and their weakness of judgement.' In both states we find an over-valuation of the subject's own mental achievements which seems senseless to a sober view; the rapid sequence of ideas in dreams is paralleled by the flight of ideas in psychoses. In both there is a complete lack of sense of time. In dreams the personality may be split - when, for instance, the dreamer's own knowledge is divided between two persons and when, in the dream, the extraneous ego corrects the actual one. This is precisely on a par with the splitting of the personality that is familiar to us in hallucinatory paranoia; the dreamer too hears his own thoughts pronounced by extraneous voices. Even chronic delusional ideas have their analogy in stereotyped recurrent pathological dreams (*le rêve obsédant*). - It not infrequently happens that after recovering from a delirium patients will say that the whole period of their illness seems to them like a not unpleasant dream: indeed they will sometimes tell us that even during the illness they have occasionally had a feeling that they are only caught up in a dream - as is often the case in dreams occurring in sleep.

After all this, it is not surprising that Radestock sums up his views, and those of many others, by declaring that 'insanity, an abnormal pathological phenomenon, is to be regarded as an intensification of the periodically recurrent normal condition of dreaming'. (Ibid., 228.)

Krauss (1859, 270 f.) has sought to establish what is perhaps a still more intimate connection between dreams and insanity than can be demonstrated by an analogy between these external manifestations. This connection he sees in their aetiology or rather in the sources of their excitation. The fundamental element common to the two states lies according to him, as we have seen, in organically determined sensations, in sensations derived from somatic stimuli, in the coenaesthesia which is based upon contributions arising from all the organs. (Cf. Peisse, 1857, 2, 21, quoted by Maury, 1878, 52.)

The indisputable analogy between dreams and insanity, extending as it does down to their characteristic details, is one of the most powerful props of the medical theory of dream-life, which regards dreaming as a useless and disturbing process and as the expression of a reduced activity of the mind. Nevertheless it is not to be expected that we shall find the ultimate explanation of dreams in the direction of mental disorders; for the unsatisfactory state of our knowledge of the origin of these latter conditions is generally recognized. It is quite likely, on the contrary, that a modification of our attitude towards dreams will at the same time affect our views upon the internal mechanism of mental disorders and that we shall be working towards an explanation of the psychoses while we are endeavouring to throw some light on the mystery of dreams.

POSTSCRIPT, 1909

The fact that I have not extended my account of the literature dealing with the problems of dreams to cover the period between the first and second editions of this book stands in need of a justification. It may strike the reader as an unsatisfactory one, but for me it was none the less decisive. The motives which led me to give any account at all of the way in which earlier writers have dealt with dreams were exhausted with the completion of this introductory chapter; to continue the task would have cost me an extraordinary effort - and the result would have been of very little use or instruction. For the intervening nine years have produced nothing new or valuable either in factual material or in opinions that might throw light on the subject. In the majority of publications that have appeared during the interval my work has remained unmentioned and unconsidered. It has, of course, received least attention from those who are engaged in what is described as 'research' into dreams, and who have thus provided a shining example of the repugnance to learning anything new which is characteristic of men of science. In the ironical words of Anatole France, '*les savants ne sont pas curieux*'. If there were such a thing in science as a right to retaliate, I should certainly be justified in my turn in disregarding the literature that has been issued since the publication of this book. The few notices of it that have appeared in scientific periodicals show so much *lack* of understanding and so much *misunderstanding* that my only reply to the critics would be to suggest their reading the book again - or perhaps, indeed, merely to suggest their reading it.

A large number of dreams have been published and analysed in accordance with my directions in papers by physicians who have decided to adopt the psycho-analytic therapeutic procedure, as well as by other authors. In so far as these writings have gone beyond a mere confirmation of my views I have included their findings in the course of my exposition. I have added a second bibliography at the end of the volume containing a list of the most important works that have appeared since this book was first published. The extensive monograph on dreams by Sante de Sanctis (1899), of which a German translation appeared soon after its issue, was published almost simultaneously with my *Interpretation of Dreams*, so that neither I nor the Italian author was able to comment upon each other's work. I have unfortunately been unable to escape the conclusion that his painstaking volume is totally deficient in ideas- so much so, in fact, that it would not even lead one to suspect the existence of the problems with which I have dealt.

Only two publications require to be mentioned which come near to my own treatment of the problems of dreams. Hermann Swoboda (1904), a youthful philosopher, has undertaken the task of extending to psychical events the discovery of a biological periodicity (in 23-day and 28-day periods) made by Wilhelm Fliess. In the course of his highly imaginative work he has endeavoured to use this key for the solution, among other problems, of the riddle of dreams. His findings would seem to underestimate the significance of dreams; the subject matter of a dream, on his view, is to be explained as an assemblage of all the memories which, on the night on which it is dreamt, complete one of the biological periods, whether for the first or for the *n*th time. A personal communication from the author led me at first to suppose that he himself no longer took this theory seriously, but it seems that this was a mistaken conclusion on my part. At a later stage I shall report upon some observations which I made in connection with Swoboda's suggestion but which led me to no convincing conclusion. I was the more pleased when, in an unexpected quarter, I made the chance discovery of a view of dreams which coincides entirely with the core of my own theory. It is impossible, for chronological reasons, that the statement in question can have been influenced by my book. I must therefore hail it as the single discoverable instance in the literature of the subject of an independent thinker who is in agreement with the essence of my theory of dreams. The book which contains the passage upon dreaming which I have in mind appeared in its second edition in 1900 under the title of *Phantasien eines Realisten* by 'Lynkeus'.¹

POSTSCRIPT, 1914

The preceding plea of justification was written in 1909. I am bound to admit that since then the situation has changed; my contribution to the interpretation of dreams is no longer neglected by writers on the subject. The new state of affairs, however, has now made it quite out of the question for me to extend my previous account of the literature. *The Interpretation of Dreams* has raised a whole series of fresh considerations and problems which have been discussed in a great variety of ways. I cannot give an account of these works, however, before I have expounded those views of my own on which they are based. I have therefore dealt with whatever seems to me of value in the latest literature at its appropriate place in the course of the discussion which now follows.

¹ [Footnote added 1930:] Cf. my paper on Josef Popper-Lynkeus and the theory of dreams (1923f).

CHAPTER II

THE METHOD OF INTERPRETING DREAMS: AN ANALYSIS OF A SPECIMEN DREAM

The title that I have chosen for my work makes plain which of the traditional approaches to the problem of dreams I am inclined to follow. The aim which I have set before myself is to show that dreams are capable of being interpreted; and any contributions I may be able to make towards the solution of the problems dealt with in the last chapter will only arise as by products in the course of carrying out my proper task. My presumption that dreams can be interpreted at once puts me in opposition to the ruling theory of dreams and in fact to every theory of dreams with the single exception of Scherner's; for 'interpreting' a dream implies assigning a 'meaning' to it - that is, replacing it by something which fits into the chain of our mental acts as a link having a validity and importance equal to the rest. As we have seen, the scientific theories of dreams leave no room for any problem of interpreting them, since in their view a dream is not a mental act at all, but a somatic process signaling its occurrence by indications registered in the mental apparatus. Lay opinion has taken a different attitude throughout the ages. It has exercised its indefeasible right to behave inconsistently; and, though admitting that dreams are unintelligible and absurd, it cannot bring itself to declare that they have no significance at all. Led by some obscure feeling, it seems to assume that, in spite of everything, every dream has a meaning, though a hidden one, that dreams are designed to take the place of some other process of thought, and that we have only to undo the substitution correctly in order to arrive at this hidden meaning.

Thus the lay world has from the earliest times concerned itself with 'interpreting' dreams and in its attempts to do so it has made use of two essentially different methods.

The first of these procedures considers the content of the dream as a whole and seeks to replace it by another content which is intelligible and in certain respects analogous to the original one. This is 'symbolic' dream-interpreting; and it inevitably breaks down when faced by dreams which are not merely unintelligible but also confused. An example of this procedure is to be seen in the explanation of Pharaoh's dream propounded by Joseph in the Bible. The seven fat kine followed by seven lean kine that ate up the fat kine - all this was a symbolic substitute for a prophecy of seven years of famine in the land of Egypt which should consume all that was brought forth in the seven years of plenty. Almost of the artificial dreams constructed by imaginative writers are designed for a symbolic interpretation of this sort: they reproduce the writer's thoughts under a disguise which is regarded as harmonizing with the recognized characteristics of dreams.¹ The idea of dreams being chiefly concerned with the future and being able to foretell it - a remnant of the old prophetic significance of dreams - provides a reason for transposing the meaning of the dream, when it has been arrived at by symbolic interpretation, into the future tense. It is of course impossible to give instructions upon the *method* of arriving at a symbolic interpretation. Success must be a question of hitting on a clever idea, of direct intuition, and for that reason it was possible for dream-interpretation by means of symbolism to be exalted into an artistic activity dependent on the possession of peculiar gifts.²

¹ [Footnote added 1909:] I found by chance in *Gradiva*, a story written by Wilhelm Jensen, a number of artificial dreams which were perfectly correctly constructed and could be interpreted just as though they had not been invented but had been dreamt by real people. In reply to an enquiry, the author confirmed the fact that he had no knowledge of my theory of dreams. I have argued that the agreement between my researches and this writer's creations is evidence in favour of the correctness of my analysis of dreams. (See Freud, 1907a.)

² [Footnote added 1914:] Aristotle remarked in this connection that the best interpreter of dreams was the man who could best grasp similarities; for dream-pictures, like pictures on water, are pulled out of shape by movement, and the most successful interpreter is the man who can detect the truth from the misshapen picture. (Büchenschütz, 1868, 65.)

The second of the two popular methods of interpreting dreams is far from making any such claims. It might be described as the '*decoding*' method, since it treats dreams as a kind of cryptography in which each sign can be translated into another sign having a known meaning, in accordance with a fixed key. Suppose, for instance, that I have dreamt of a letter and also of a funeral. If I consult a 'dream-book', I find that 'letter' must be translated by 'trouble' and 'funeral' by 'betrothal'. It then remains for me to link together the key words which I have deciphered in this way and, once more, to transpose the result into the future tense. An interesting modification of the process of decoding, which to some extent corrects the purely mechanical character of its method of transposing, is to be found in the book written upon the interpretation of dreams by Artemidorus of Daldis.¹ This method takes into account not only the content of the dream but also the character and circumstances of the dreamer; so that the same dream-element will have a different meaning for a rich man, a married man or, let us say, an orator, from what it has for a poor man, a bachelor or a merchant. The essence of the decoding procedure, however, lies in the fact that the work of interpretation is not brought to bear on the dream as a whole but on each portion of the dream's content independently, as though the dream were a geological conglomerate in which each fragment of rock required a separate assessment. There can be no question that the invention of the decoding method of interpretation was suggested by disconnected and confused dreams.²

¹ [Footnote added 1914:] Artemidorus of Daldis, who was probably born at the beginning of the second century A.D., has left us the most complete and painstaking study of dream-interpretation as practised in the Graeco-Roman world. As Theodor Gomperz (1866, 7 f.) points out, he insisted on the importance of basing the interpretation of dreams on observation and experience, and made a rigid distinction between his own art and others that were illusory. The principle of his interpretative art, according to Gomperz, is identical with magic, the principle of association. A thing in a dream means what it recalls to the mind - to the dream-interpreter's mind, it need hardly be said. An insuperable source of arbitrariness and uncertainty arises from the fact that the dream-element may recall various things to the interpreter's mind and may recall something different to different interpreters. The technique which I describe in the pages that follow differs in one essential respect from the ancient method: it imposes the task of interpretation upon the dreamer himself. It is not concerned with what occurs to the *interpreter* in connection with a particular element of the dream, but with what occurs to the *dreamer*. - Recent reports, however, from a missionary, Father Tfinkdji (1913), show that modern dream-interpreters in the East also make free use of the dreamer's collaboration. He writes as follows of dream-interpreters among the Arabs of Mesopotamia: 'Pour interpréter exactement un songe, les oniromanciens les plus habiles s'informent de ceux qui les consultent de toutes les circonstances qu'ils regardent nécessaires pour la bonne explication. . . . En un mot, nos oniromanciens ne laissent aucune circonstance leur échapper et ne donnent l'interprétation désirée avant d'avoir parfaitement saisi et reçu toutes les interrogations désirables.' ['In order to give a precise interpretation of a dream, the most skilful dream-diviners find out from those who consult them all the circumstances which they consider essential in order to arrive at a right explanation. . . . In short, these dream-diviners do not allow a single point to escape them and only give their interpretation after they have completely mastered the replies to all the necessary enquiries.'] Among these enquiries are habitually included questions as to the dreamer's closest family relations - his parents, wife and children - as well as such a typical formula as: 'Habuistine in hac nocte copulam conjugam ante vel post somnium?' ['Did you copulate with your wife that night before or after you had the dream?'] - 'L'idée dominante dans l'interprétation des songes consiste à expliquer le rêve par son opposée.' ['The principal idea in interpreting dreams lies in explaining a dream by its opposite.']

² [Footnote added 1909:] Dr. Alfred Robitsek has pointed out to me that the oriental 'dream-books' (of which ours are wretched imitations) base the greater number of their interpretations of dream-elements upon similarity of sounds and resemblance between words. The fact that these connections inevitably disappear in translation accounts for the unintelligibility of the renderings in our own popular dream-books. The extraordinarily important part played by punning and verbal quibbles in the ancient civilizations of the East may be studied in the writings of Hugo Winckler. - [Added 1911:] The nicest instance of a dream-interpretation which has reached us from ancient times is based on a play upon words. It is told by Artemidorus: 'I think too that Aristander gave a most happy interpretation to Alexander of Macedon when he had surrounded Tyre and was besieging it but was feeling uneasy and disturbed because of the length of time the siege was taking. Alexander dreamt he saw a satyr dancing on his shield. Aristander happened to be in the neighbourhood of Tyre, in attendance on the king during his Syrian campaign. By dividing the word for satyr into *σά* and *τύρος* he encouraged the king to press home the siege so that he became master of the city.' (*σά Τύρος* = Tyre is thine.) - Indeed, dreams are so closely related to linguistic expression that Ferenczi has truly remarked that every tongue has its own dream-language. It is impossible as a rule to translate a dream into a foreign language and this is equally true, I fancy, of a book such as the present one. [Added 1930:] Nevertheless, Dr. A. A. Brill of New York, and others after him, have succeeded in translating *The Interpretation of Dreams*.

It cannot be doubted for a moment that neither of the two popular procedures for interpreting dreams can be employed for a scientific treatment of the subject. The symbolic method is restricted in its application and incapable of being laid down on general lines. In the case of the decoding method everything depends on the trustworthiness of the 'key' - the dream-book, and of this we have no guarantee. Thus one might feel tempted to agree with the philosophers and the psychiatrists and, like them, rule out the problem of dream-interpretation as a purely fanciful task.¹

But I have been taught better. I have been driven to realize that here once more we have one of those not infrequent cases in which an ancient and jealously held popular belief seems to be nearer the truth than the judgement of the prevalent science of today. I must affirm that dreams really have a meaning and that a scientific procedure for interpreting them is possible.

My knowledge of that procedure was reached in the following manner. I have been engaged for many years (with a therapeutic aim in view) in unravelling certain psychopathological structures - hysterical phobias, obsessional ideas, and so on. I have been doing so, in fact, ever since I learnt from an important communication by Josef Breuer that as regards these structures (which are looked on as pathological symptoms) unravelling these coincides with removing them. (Cf. Breuer and Freud, 1895.) If a pathological idea of this sort can be traced back to the elements in the patient's mental life from which it originated, it simultaneously crumbles away and the patient is freed from it. Considering the impotence of our other therapeutic efforts and the puzzling nature of these disorders, I felt tempted to follow the path marked out by Breuer, in spite of every difficulty, till a complete explanation was reached. I shall have on another occasion to report at length upon the form finally taken by this procedure and the results of my labours. It was in the course of these psycho-analytic studies that I came upon dream-interpretation. My patients were pledged to communicate to me every idea or thought that occurred to them in connection with some particular subject; amongst other things they told me their dreams and so taught me that a dream can be inserted into the psychical chain that has to be traced backwards in the memory from a pathological idea. It was then only a short step to treating the dream itself as a symptom and to applying to dreams the method of interpretation that had been worked out for symptoms.

¹ After I had completed my manuscript I came across a work by Stumpf (1889) which agrees with my views in seeking to prove that dreams have a meaning and can be interpreted. He effects his interpretation, however, by means of a symbolism of an allegorical character without any guarantee of the general validity of his procedure.

This involves some psychological preparation of the patient. In the attention he pays to his own psychical perceptions and the elimination of the criticism by which he normally sifts the thoughts that occur to him. In order that he may be able to concentrate his attention on his self-observation it is an advantage for him to lie in a restful attitude and shut his eyes. It is necessary to insist explicitly on his renouncing all criticism of the thoughts that he perceives. We therefore tell him that the success of the psycho-analysis depends on his noticing and reporting whatever comes into his head and not being misled, for instance, into suppressing an idea because it strikes him as unimportant or irrelevant or because it seems to him meaningless. He must adopt a completely impartial attitude to what occurs to him, since it is precisely his critical attitude which is responsible for his being unable, in the ordinary course of things, to achieve the desired unravelling of his dream or obsessional idea or whatever it may be.

I have noticed in my psycho-analytical work that the whole frame of mind of a man who is reflecting is totally different from that of a man who is observing his own psychical processes. In reflection there is one more psychical activity at work than in the most attentive self-observation, and this is shown amongst other things by the tense looks and wrinkled forehead of a person pursuing his reflections as compared with the restful expression of a self-observer. In both cases attention must be concentrated, but the man who is reflecting is also exercising his *critical* faculty; this leads him to reject some of the ideas that occur to him after perceiving them, to cut short others without following the trains of thought which they would open up to him, and to behave in such a way towards still others that they never become conscious at all and are accordingly suppressed before being perceived. The self-observer on the other hand need only take the trouble to suppress his critical faculty. If he succeeds in doing that, innumerable ideas come into his consciousness of which he could otherwise never have got hold. The material which is in this way freshly obtained for his self-perception makes it possible to interpret both his pathological ideas and his dream-structures. What is in question, evidently, is the establishment of a psychical state which, in its distribution of psychical energy (that is, of mobile attention), bears some analogy to the state before falling asleep - and no doubt also to hypnosis. As we fall asleep, 'involuntary ideas' emerge, owing to the relaxation of a certain deliberate (and no doubt also critical) activity which we allow to influence the course of our ideas while we are awake. (We usually attribute this relaxation to 'fatigue'.) As the involuntary ideas emerge they change into visual and acoustic images. (Cf. the remarks by Schleiermacher and others quoted above on p. 559 f.)¹ In the state used for the analysis of dreams and pathological ideas, the patient purposely and deliberately abandons this activity and employs the psychical energy thus saved (or a portion of it) in attentively following the involuntary thoughts which now emerge, and which - and here the situation differs from that of falling asleep - retain the character of ideas. *In this way the 'involuntary' ideas are transformed into voluntary ones.*

¹ [Footnote added 1919:] Silberer (1909, 1910 and 1912) has made important contributions to dream-interpretation by directly observing this transformation of ideas into visual images.

The adoption of the required attitude of mind towards ideas that seem to emerge 'of their own free will' and the abandonment of the critical function that is normally in operation against them seem to be hard of achievement for some people. The 'involuntary thoughts' are liable to release a most violent resistance, which seeks to prevent their emergence. If we may trust that great poet and philosopher Friedrich Schiller, however, poetic creation must demand an exactly similar attitude. In a passage in his correspondence with Körner - we have to thank Otto Rank for unearthing it - Schiller (writing on December 1, 1788) replies to his friend's complaint of insufficient productivity: 'The ground for your complaint seems to me to lie in the constraint imposed by your reason upon your imagination. I will make my idea more concrete by a simile. It seems a bad thing and detrimental to the creative work of the mind if Reason makes too close an examination of the ideas as they come pouring in - at the very gateway, as it were. Looked at in isolation, a thought may seem very trivial or very fantastic; but it may be made important by another thought that comes after it, and, in conjunction with other thoughts that may seem equally absurd, it may turn out to form a most effective link. Reason cannot form any opinion upon all this unless it retains the thought long enough to look at it in connection with the others. On the other hand, where there is a creative mind, Reason - so it seems to me - relaxes its watch upon the gates, and the ideas rush in pell-mell, and only then does it look them through and examine them in a mass. - You critics, or whatever else you may call yourselves, are ashamed or frightened of the momentary and transient extravagances which are to be found in all truly creative minds and whose longer or shorter duration distinguishes the thinking artist from the dreamer. You complain of your unfruitfulness because you reject too soon and discriminate too severely.'

Nevertheless, what Schiller describes as a relaxation of the watch upon the gates of Reason, the adoption of an attitude of uncritical self-observation, is by no means difficult. Most of my patients achieve it after their first instructions. I myself can do so very completely, by the help of writing down my ideas as they occur to me. The amount of psychical energy by which it is possible to reduce critical activity and increase the intensity of self-observation varies considerably according to the subject on which one is trying to fix one's attention.

Our first step in the employment of this procedure teaches us that what we must take as the object of our attention is not the dream as a whole but the separate portions of its content. If I say to a patient who is still a novice: 'What occurs to you in connection with this dream?', as a rule his mental horizon becomes a blank. If, however, I put the dream before him cut up into pieces, he will give me a series of associations to each piece, which might be described as the 'background thoughts' of that particular part of the dream. Thus the method of dream interpretation which I practise already differs in this first important respect from the popular, historic and legendary method of interpretation by means of symbolism and approximates to the second or 'decoding' method. Like the latter, it employs interpretation *en détail* and not *en masse*; like the latter, it regards dreams from the very first as being of a composite character, as being conglomerates of psychical formations.

In the course of my psycho-analyses of neurotics I must already have analysed over a thousand dreams; but I do not propose to make use of this material in my present introduction to the technique and theory of dream-interpretation. Apart from the fact that such a course would be open to the objection that these are the dreams of neuropaths, from which no valid inferences could be made as to the dreams of normal people, there is quite another reason which forces this decision upon me. The subject to which these dreams of my patients lead up is always, of course, the case history which underlies their neurosis. Each dream would therefore necessitate a lengthy introduction and an investigation of the nature and aetiological determinants of the psychoneuroses. But these questions are in themselves novelties and highly bewildering and would distract attention from the problem of dreams. On the contrary, it is my intention to make use of my present elucidation of dreams as a preliminary step towards solving the more difficult problems of the psychology of the neuroses. If, however, I forego my principal material, the dreams of my neurotic patients, I must not be too particular about what is left to me. All that remains are such dreams as have been reported to me from time to time by normal persons of my acquaintance, and such others as have been quoted as instances in the literature dealing with dream-life. Unluckily, however, none of these dreams are accompanied by the analysis without which I cannot discover a dream's meaning. My procedure is not so convenient as the popular decoding method which translates any given piece of a dream's content by a fixed key. I, on the contrary, am prepared to find that the same piece of content may conceal a different meaning when it occurs in various people or in various contexts. Thus it comes about that I am led to my own dreams, which offer a copious and convenient material, derived from an approximately normal person and relating to multifarious occasions of daily life. No doubt I shall be met by doubts of the trustworthiness of 'self-analyses' of this kind; and I shall be told that they leave the door open to arbitrary conclusions. In my judgement the situation is in fact more favourable in the case of *self*-observation than in that of other people; at all events we may make the experiment and see how far self-analysis takes us with the interpretation of dreams. But I have other difficulties to overcome, which lie within myself. There is some natural hesitation about revealing so many intimate facts about one's mental life; nor can there be any guarantee against misinterpretation by strangers. But it must be possible to overcome such hesitations. 'Tout psychologue', writes Delboeuf, 'est obligé de faire l'aveu même de ses faiblesses s'il croit par là jeter du jour sur quelque problème obscur.'¹ And it is safe to assume that my readers too will very soon find their initial interest in the indiscretions which I am bound to make replaced by an absorbing immersion in the psychological problems upon which they throw light.²

¹ ['Every psychologist is under an obligation to confess even his own weaknesses, if he thinks that it may throw light upon some obscure problem.']

² I am obliged to add, however, by way of qualification of what I have said above, that in scarcely any instance have I brought forward the *complete* interpretation of one of my own dreams, as it is known to me. I have probably been wise in not putting too much faith in my readers' discretion.

Accordingly I shall proceed to choose out one of my own dreams and demonstrate upon it my method of interpretation. In the case of every such dream some remarks by way of preamble will be necessary. - And now I must ask the reader to make my interests his own for quite a while, and to plunge, along with me, into the minutest details of my life; for a transference of this kind is peremptorily demanded by our interest in the hidden meaning of dreams.

PREAMBLE

During the summer of 1895 I had been giving psycho-analytic treatment to a young lady who was on very friendly terms with me and my family. It will be readily understood that a mixed relationship such as this may be a source of many disturbed feelings in a physician and particularly in a psychotherapist. While the physician's personal interest is greater, his authority is less; any failure would bring a threat to the old-established friendship with the patient's family. This treatment had ended in a partial success; the patient was relieved of her hysterical anxiety but did not lose all her somatic symptoms. At that time I was not yet quite clear in my mind as to the criteria indicating that a hysterical case history was finally closed, and I proposed a solution to the patient which she seemed unwilling to accept. While we were thus at variance, we had broken off the treatment for the summer vacation. - One day I had a visit from a junior colleague, one of my oldest friends, who had been staying with my patient, Irma, and her family at their country resort. I asked him how he had found her and he answered: 'She's better, but not quite well.' I was conscious that my friend Otto's words, or the tone in which he spoke them, annoyed me. I fancied I detected a reproof in them, such as to the effect that I had promised the patient too much; and, whether rightly or wrongly, I attributed the supposed fact of Otto's siding against me to the influence of my patient's relatives, who, as it seemed to me, had never looked with favour on the treatment. However, my disagreeable impression was not clear to me and I gave no outward sign of it. The same evening I wrote out Irma's case history, with the idea of giving it to Dr. M. (a common friend who was at that time the leading figure in our circle) in order to justify myself. That night (or more probably the next morning) I had the following dream, which I noted down immediately after waking.¹

¹ [*Footnote added 1914:*] This is the first dream which I submitted to a detailed interpretation.

DREAM OF JULY 23RD-24TH, 1895

A large hall - numerous guests, whom we were receiving. -Among them was Irma. I at once took her on one side, as though to answer her letter and to reproach her for not having accepted my 'solution' yet. I said to her: 'If you still get pains, its really only your fault.' She replied: 'If you only knew what pains I've got now in my throat and stomach and abdomen - its choking me' -I was alarmed and looked at her. She looked pale and puffy. I thought to myself that after all I must be missing some organic trouble. I took her to the window and looked down her throat, and she showed signs of recalcitrance, like women with artificial dentures. I thought to myself that there was really no need for her to do that. - She then opened her mouth properly and on the right I found a big white patch; at another place I saw extensive whitish grey scabs upon some remarkable curly structures which were evidently modelled on the turbinal bones of the nose. - I at once called in Dr. M., and he repeated the examination and confirmed it . . . Dr M. looked quite different from usual; he was very pale, he walked with a limp and his chin was clean-shaven. . . . My friend Otto was now standing beside her as well, and my friend Leopold was percussing her through her bodice and saying: 'She has a dull area low down on her left.' He also indicated that a portion of the skin on the left shoulder was infiltrated. (I noticed this, just as he did, in spite of her dress.) . . . M. said 'There's no doubt its an infection, but no matter; dysentery will supervene and the toxin will eliminated' . . . We were directly aware, too, of the origin of her infection. Not long before, when she was feeling unwell, my friend Otto had given her an injection of a preparation of propyl, propyls . . . propionic acid. . . . trimethylamin (and I saw before me the formula for this printed in heavy type). . . . Injections of that sort ought not to be made so thoughtlessly And probably the syringe had not been clean.

This dream has one advantage over many others. It was immediately clear what events of the previous day provided its starting-point. My preamble makes that plain. The news which Otto had given me of Irma's condition and the case history which I had been engaged in writing till far into the night continued to occupy my mental activity even after I was asleep. Nevertheless, no one who had only read the preamble and the content of the dream itself could have the slightest notion of what the dream meant. I myself had no notion. I was astonished at the symptoms of which Irma complained to me in the dream, since they were not the same as those for which I had treated her. I smiled at the senseless idea of an injection of propionic acid and at Dr. M.'s consoling reflections. Towards its end the dream seemed to me to be more obscure and compressed than it was at the beginning. In order to discover the meaning of all this it was necessary to undertake a detailed analysis.

ANALYSIS

The hall - numerous guests whom we were receiving. We were spending that summer at Bellevue, a house standing by itself on one of the hills adjoining the Kahlenberg. The house had formerly been designed as a place of entertainment and its reception-rooms were in consequence unusually lofty and hall like. It was at Bellevue that I had the dream, a few days before my wife's birthday. On the previous day my wife had told me that she expected that a number of friends, including Irma, would be coming out to visit us on her birthday. My dream was thus anticipating this occasion: it was my wife's birthday and a number of guests, including Irma, were being received by us in the large hall at Bellevue.

I reproached Irma for not having accepted my solution. I said: 'If you still get pains, it's your own fault.' I might have said this to her in waking life, and I may actually have done so. It was my view at that time (though I have since recognized it as a wrong one) that my task was fulfilled when I had informed a patient of the hidden meaning of his symptoms: I considered that I was not responsible for whether he accepted the solution or not - though this was what success depended on. I owe it to this mistake, which I have now fortunately corrected, that my life was made easier at a time when, in spite of all my inevitable ignorance, I was expected to produce therapeutic successes. - I noticed, however, that the words which I spoke to Irma in the dream showed that I was specially anxious not to be responsible for the pains which she still had. If they were her fault they could not be mine. Could it be that the purpose of the dream lay in this direction?

Irma's complaint: pains in her throat and abdomen and stomach; it was choking her. Pains in the stomach were among my patient's symptoms but were not very prominent; she complained more of feelings of nausea and disgust. Pains in the throat and abdomen and constriction of the throat played scarcely any part in her illness. I wondered why I decided upon this choice of symptoms in the dream but could not think of an explanation at the moment.

She looked pale and puffy. My patient always had a rosy complexion. I began to suspect that someone else was being substituted for her.

I was alarmed at the idea that I had missed an organic illness. This, as may well be believed, is a perpetual source of anxiety to a specialist whose practice is almost limited to neurotic patients and who is in the habit of attributing to hysteria a great number of symptoms which other physicians treat as organic. On the other hand, a faint doubt crept into my mind - from where, I could not tell - that my alarm was not entirely genuine. If Irma's pains had an organic basis, once again I could not be held responsible for curing them; my treatment only set out to get rid of *hysterical* pains. It occurred to me, in fact, that I was actually *wishing* that there had been a wrong diagnosis; for, if so, the blame for my lack of success would also have been got rid of.

I took her to the window to look down her throat. She showed some recalcitrance, like women with false teeth. I thought to myself that really there was no need for her to do that. I had never had any occasion to examine Irma's oral cavity. What happened in the dream reminded me of an examination I had carried out some time before of a governess: at a first glance she had seemed a picture of youthful beauty, but when it came to opening her mouth she had taken measures to conceal her plate. This led to recollections of other medical examinations and of little secrets revealed in the course of them - to the satisfaction of neither party.¹ *There was really no need for her to do that* was no doubt intended in the first place as a compliment to Irma; but I suspected that it had another meaning besides. (If one carries out an analysis attentively, one gets a feeling of whether or not one has exhausted all the background thoughts that are to be expected.) The way in which Irma stood by the window suddenly reminded me of another experience. Irma had an intimate woman friend of whom I had a very high opinion. When I visited this lady one evening I had found her by a window in the situation reproduced in the dream, and her physician, the same Dr. M., had pronounced that she had a diphtheritic membrane. The figure of Dr. M. and the membrane reappear later in the dream. It now occurred to me that for the last few months I had had every reason to suppose that this other lady was also a hysteric. Indeed, Irma herself had betrayed the fact to me. What did I know of her condition? One thing precisely: that, like my Irma of the dream, she suffered from hysterical choking. So in the dream I had replaced my patient by her friend. I now recollected that I had often played with the idea that she too might ask me to relieve her of her symptoms. I myself, however, had thought this unlikely, since she was of a very reserved nature. She was *recalcitrant*, as was shown in the dream. Another reason was that *there was need for her to do it*: she had so far shown herself strong enough to master her condition without outside help. There still remained a few features that I could not attach either to Irma or to her friend: *pale; puffy; false teeth*. The false teeth took me to the governess whom I have already mentioned; I now felt inclined to be satisfied with *bad* teeth. I then thought of someone else to whom these features might be alluding. She again was not one of my patients, nor should I have liked to have her as a patient, since I had noticed that she was bashful in my presence and I could not think she would make an amenable patient. She was usually pale, and once, while she had been in specially good health, she had looked puffy.¹ Thus I had been comparing my patient Irma with two other people who would also have been recalcitrant to treatment. What could the reason have been for my having exchanged her in the dream for her friend? Perhaps it was that I should have *liked* to exchange her: either I felt more sympathetic towards her friend or had a higher opinion of her intelligence. For Irma seemed to me foolish because she had not accepted my solution. Her friend would have been wiser, that is to say she would have yielded sooner. She would then have *opened her mouth properly*, and have told me more than Irma.²

¹ The still unexplained complaint about *pains in the abdomen* could also be traced back to this third figure. The person in question was, of course, my own wife; the pains in the abdomen reminded me of one of the occasions on which I had noticed her bashfulness. I was forced to admit to myself that I was not treating either Irma or my wife very kindly in this dream; but it should be observed by way of excuse that I was measuring them both by the standard of the good and amenable patient.

² I had a feeling that the interpretation of this part of the dream was not carried far enough to make it possible to follow the whole of its concealed meaning. If I had pursued my comparison between the three women, it would have taken me far afield. There is at least one spot in every dream at which it is unplumbable - a navel, as it were, that is its point of contact with the unknown.

What I saw in her throat: a white patch and turbinal bones with scabs on them. The white patch reminded me of diphtheritis and so of Irma's friend, but also of a serious illness of my eldest daughter's almost two years earlier and of the fright I had had in those anxious days. The scabs on the turbinal bones recalled a worry about my own state of health. I was making frequent use of cocaine at that time to reduce some troublesome nasal swellings, and I had heard a few days earlier that one of my women patients who had followed my example had developed an extensive necrosis of the nasal mucous membrane. I had been the first to recommend the use of cocaine, in 1885, and this recommendation had brought serious reproaches down on me. The misuse of that drug had hastened the death of a dear friend of mine. This had been before 1895.

I at once called in Dr. M., and he repeated the examination. This simply corresponded to the position occupied by M. in our circle. But the '*at once*' was sufficiently striking to require a special explanation. It reminded me of a tragic event in my practice. I had on one occasion produced a severe toxic state in a woman patient by repeatedly prescribing what was at that time regarded as a harmless remedy (sulphonal), and had hurriedly turned for assistance and support to my experienced senior colleague. There was a subsidiary detail which confirmed the idea that I had this incident in mind. My patient - who succumbed to the poison - had the same name as my eldest daughter. It had never occurred to me before, but it struck me now almost like an act of retribution on the part of destiny. It was as though the replacement of one person by another was to be continued in another sense: this Mathilde for that Mathilde, an eye for an eye and a tooth for a tooth. It seemed as if I had been collecting all the occasions which I could bring up against myself as evidence of lack of medical conscientiousness.

Dr. M. was pale, had a clean-shaven chin and walked with a limp. This was true to the extent that his unhealthy appearance often caused his friends anxiety. The two other features could only apply to someone else. I thought of my elder brother, who lives abroad, who is clean-shaven and whom, if I remembered right, the M. of the dream closely resembled. We had had news a few days earlier that he was walking with a limp owing to an arthritic affection of his hip. There must, I reflected, have been some reason for my fusing into one the two figures in the dream. I then remembered that I had a similar reason for being in an ill-humour with each of them: they had both rejected a certain suggestion I had recently laid before them.

My friend Otto was now standing beside the patient and my friend Leopold was examining her and indicated that there was a dull area low down on the left. My friend Leopold was also a physician and a relative of Otto's. Since they both specialized in the same branch of medicine, it was their fate to be in competition with each other, and comparisons were constantly being drawn between them. Both of them acted as my assistants for years while I was still in charge of the neurological out-patients' department of a children's hospital. Scenes such as the one represented in the dream used often to occur there. While I was discussing the diagnosis of a case with Otto, Leopold would be examining the child once more and would make an unexpected contribution to our decision. The difference between their characters was like that between the bailiff Bräsig and his friend Karl: one was distinguished for his quickness, while the other was slow but sure. If in the dream I was contrasting Otto with the prudent Leopold, I was evidently doing so to the advantage of the latter. The comparison was similar to the one between my disobedient patient Irma and the, friend whom I regarded as wiser than she was. I now perceived another of the lines along which the chain of thought in the dream branched off: from the sick child to the children's hospital. - *The dull area low down on the left* seemed to me to agree in every detail with one particular case in which Leopold had struck me by his thoroughness. I also had a vague notion of something in the nature of a metastatic affection; but this may also have been a reference to the patient whom I should have liked to have in the place of Irma. So far as I had been able to judge, she had produced an imitation of a tuberculosis.

A portion of the skin on the left shoulder was infiltrated. I saw at once that this was the rheumatism in my own shoulder, which I invariably notice if I sit up late into the night. Moreover the wording in the dream was most ambiguous: '*I noticed this, just as he did . . .*' I noticed it in my own body, that is. I was struck, too, by the unusual phrasing: 'a portion of the skin was infiltrated.' We are in the habit of speaking of 'a left upper posterior infiltration', and this would refer to the lung and so once more to tuberculosis.

In spite of her dress. This was in any case only an interpolation. We naturally used to examine the children in the hospital undressed: and this would be a contrast to the manner in which adult female patients have to be examined. I remembered that it was said of a celebrated clinician that he never made a physical examination of his patients except through their clothes. Further than this I could not see. Frankly, I had no desire to penetrate more deeply at this point.

Dr. M. said: 'Its an infection, but no matter. Dysentery will supervene and the toxin will be eliminated.' At first this struck me as ridiculous. But nevertheless, like all the rest, it had to be carefully analysed. When I came to look at it more closely it seemed to have some sort of meaning all the same. What I discovered in the patient was a local diphtheritis. I remembered from the time of my daughter's illness a discussion on diphtheritis and diphtheria, the latter being the general infection that arises from the local diphtheritis. Leopold indicated the presence of a general infection of this kind from the existence of a dull area, which might thus be regarded as a metastatic focus. I seemed to think, it is true, that metastases like this do not in fact occur with diphtheria: it made me think rather of pyaemia.

No matter. This was intended as a consolation. It seemed to fit into the context as follows. The content of the preceding part of the dream had been that my patient's pains were due to a severe organic affection. I had a feeling that I was only trying in that way to shift the blame from myself. Psychological treatment could not be held responsible for the persistence of diphtheritic pains. Nevertheless I had a sense of awkwardness at having invented such a severe illness for Irma simply in order to clear myself. It looked so cruel. Thus I was in need of an assurance that all would be well in the end, and it seemed to me that to have put the consolation into the mouth precisely of Dr. M. had not been a bad choice. But here I was taking up a superior attitude towards the dream, and this itself required explanation.

And why was the consolation so nonsensical?

Dysentery. There seemed to be some remote theoretical notion that morbid matter can be eliminated through the bowels. Could it be that I was trying to make fun of Dr. M.'s fertility in producing far-fetched explanations and making unexpected pathological connections? Something else now occurred to me in relation to dysentery. A few months earlier I had taken on the case of a young man with remarkable difficulties associated with defaecating, who had been treated by other physicians as a case of 'anaemia accompanied by malnutrition'. I had recognized it as a hysteria, but had been unwilling to try him with my psychotherapeutic treatment and had sent him on a sea voyage. Some days before, I had had a despairing letter from him from Egypt, saying that he had had a fresh attack there which a doctor had declared was dysentery. I suspected that the diagnosis was an error on the part of an ignorant practitioner who had allowed himself to be taken in by the hysteria. But I could not help reproaching myself for having put my patient in a situation in which he might have contracted some organic trouble on top of his hysterical intestinal disorder. Moreover, 'dysentery' sounds not unlike 'diphtheria' - a word of ill omen which did not occur in the dream.

Yes, I thought to myself, I must have been making fun of Dr. M. with the consoling prognosis 'Dysentery will supervene', etc.: for it came back to me that, years before, he himself had told an amusing story of a similar kind about another doctor. Dr. M. had been called in by him for consultation over a patient who was seriously ill, and had felt obliged to point out, in view of the very optimistic view taken by his colleague, that he had found albumen in the patient's urine. The other, however, was not in the least put out: '*No matter*', he had said, 'the albumen will soon be eliminated!' - I could no longer feel any doubt, therefore, that this part of the dream was expressing derision at physicians who are ignorant of hysteria. And, as though to confirm this, a further idea crossed my mind: 'Does Dr. M. realize that the symptoms in his patient (Irma's friend) which give grounds for fearing tuberculosis also have a hysterical basis? Has he spotted this hysteria? or has he been taken in by it?'

But what could be my motive for treating this friend of mine so badly? That was a very simple matter. Dr. M. was just as little in agreement with my 'solution' as Irma herself. So I had already revenged myself in this dream on two people: on Irma with the words 'If you still get pains, it's your own fault', and on Dr. M. by the wording of the nonsensical consolation that I put into his mouth.

We were directly aware of the origin of the infection. This direct knowledge in the dream was remarkable. Only just before we had had no knowledge of it, for the infection was only revealed by Leopold.

When she was feeling unwell, my friend Otto had given her an injection. Otto had in fact told me that during his short stay with Irma's family he had been called in to a neighbouring hotel to give an injection to someone who had suddenly felt unwell. These injections reminded me once more of my unfortunate friend who had poisoned himself with cocaine. I had advised him to use the drug internally only, while morphia was being withdrawn; but he had at once given himself cocaine *injections*.

A preparation of propyl . . . propyls . . . propionic acid. How could I have come to think of this? During the previous evening, before I wrote out the case history and had the dream, my wife had opened a bottle of liqueur, on which the word 'Ananas'¹ appeared and which was a gift from our friend Otto: for he has a habit of making presents on every possible occasion. It was to be hoped, I thought to myself, that some day he would find a wife to cure him of the habit. This liqueur gave off such a strong smell of fusel oil that I refused to touch it. My wife suggested our giving the bottle to the servants, but I - with even greater prudence - vetoed the suggestion, adding in a philanthropic spirit that there was no need for *them* to be poisoned either. The smell of fusel oil (amyl . . .) evidently stirred up in my mind a recollection of the whole series - propyl, methyl, and so on - and this accounted for the propyl preparation in the dream. It is true that I carried out a substitution in the process: I dreamt of propyl after having smelt amyl. But substitutions of this kind are perhaps legitimate in organic chemistry.

Trimethylamin. I saw the chemical formula of this substance in my dream, which bears witness to a great effort on the part of my memory. Moreover, the formula was printed in heavy type, as though there had been a desire to lay emphasis on some part of the context as being of quite special importance. What was it, then, to which my attention was to be directed in this way by trimethylamin? It was to a conversation with another friend who had for many years been familiar with all my writings during the period of their gestation, just as I had been with his. He had at that time confided some ideas to me on the subject of the chemistry of the sexual processes, and had mentioned among other things that he believed that one of the products of sexual metabolism was trimethylamin. Thus this substance led me to sexuality, the factor to which I attributed the greatest importance in the origin of the nervous disorders which it was my aim to cure. My patient Irma was a young widow; if I wanted to find an excuse for the failure of my treatment in her case, what I could best appeal to would no doubt be this fact of her widowhood, which her friends would be so glad to see changed. And how strangely, I thought to myself, a dream like this is put together! The other woman, whom I had as a patient in the dream instead of Irma, was also a young widow.

¹ I must add that the sound of the word 'Ananas' bears a remarkable resemblance to that of my patient Irma's family name.

I began to guess why the formula for trimethylamin had been so prominent in the dream. So many important subjects converged upon that one word. Trimethylamin was an allusion not only to the immensely powerful factor of sexuality, but also to a person whose agreement I recalled with satisfaction whenever I felt isolated in my opinions. Surely this friend who played so great a part in my life must appear again elsewhere in these trains of thought. Yes. For he had a special knowledge of the consequences of affections of the nose and its accessory cavities; and he had drawn scientific attention to some very remarkable connections between the turbinal bones and the female organs of sex. (Cf. the three curly structures in Irma's throat.) I had had Irma examined by him to see whether her gastric pains might be of nasal origin. But he suffered himself from suppurative rhinitis, which caused me anxiety; and no doubt there was an allusion to this in the pyaemia which vaguely came into my mind in connection with the metastases in the dream.

Injections of that sort ought not to be made so thoughtlessly. Here an accusation of thoughtlessness was being made directly against my friend Otto. I seemed to remember thinking something of the same kind that afternoon when his words and looks had appeared to show that he was siding against me. It had been some such notion as: 'How easily his thoughts are influenced! How thoughtlessly he jumps to conclusions!' - Apart from this, this sentence in the dream reminded me once more of my dead friend who had so hastily resorted to cocaine injections. As I have said, I had never contemplated the drug being given by injection. I noticed too that in accusing Otto of thoughtlessness in handling chemical substances I was once more touching upon the story of the unfortunate Mathilde, which gave grounds for the same accusation against myself. Here I was evidently collecting instances of my conscientiousness, but also of the reverse.

And probably the syringe had not been clean. This was yet another accusation against Otto, but derived from a different source. I had happened the day before to meet the son of an old lady of eighty-two, to whom I had to give an injection of morphia twice a day. At the moment she was in the country and he told me that she was suffering from phlebitis. I had at once thought it must be an infiltration caused by a dirty syringe. I was proud of the fact that in two years I had not caused a single infiltration; I took constant pains to be sure that the syringe was clean. In short, I was conscientious. The phlebitis brought me back once more to my wife, who had suffered from thrombosis during one of her pregnancies; and now three similar situations came to my recollection involving my wife, Irma and the dead Mathilde. The identity of these situations had evidently enabled me to substitute the three figures for one another in the dream.

I have now completed the interpretation of the dream.¹ While I was carrying it out I had some difficulty in keeping at bay all the ideas which were bound to be provoked by a comparison between the content of the dream and the concealed thoughts lying behind it. And in the meantime the 'meaning' of the dream was borne in upon me. I became aware of an intention which was carried into effect by the dream and which must have been my motive for dreaming it. The dream fulfilled certain wishes which were started in me by the events of the previous evening (the news given me by Otto and my writing out of the case history). The conclusion of the dream, that is to say, was that I was not responsible for the persistence of Irma's pains, but that Otto was. Otto had in fact annoyed me by his remarks about Irma's incomplete cure, and the dream gave me my revenge by throwing the reproach back on to him. The dream acquitted me of the responsibility for Irma's condition by showing that it was due to other factors - it produced a whole series of reasons. The dream represented a particular state of affairs as I should have wished it to be. *Thus its content was the fulfilment of a wish and its motive was a wish.*

¹ [Footnote added 1909] Though it will be understood that I have not reported everything that occurred to me during the process of interpretation.

Thus much leapt to the eyes. But many of the details of the dream also became intelligible to me from the point of view of wish-fulfilment. Not only did I revenge myself on Otto for being too hasty in taking sides against me by representing him as being too hasty in his medical treatment (in giving the injection); but I also revenged myself on him for giving me the bad liqueur which had an aroma of fusel oil. And in the dream I found an expression which united the two reproaches: the injection was of a preparation of propyl. This did not satisfy me and I pursued my revenge further by contrasting him with his more trustworthy competitor. I seemed to be saying: 'I like *him* better than *you*.' But Otto was not the only person to suffer from the vials of my wrath. I took revenge as well on my disobedient patient by exchanging her for one who was wiser and less recalcitrant. Nor did I allow Dr. M. to escape the consequences of his contradiction but showed him by means of a clear allusion that he was an ignoramus on the subject. ('*Dysentery will supervene*', etc.) Indeed I seemed to be appealing from him to someone else with greater knowledge (to my friend who had told me of trimethylamin) just as I had turned from Irma to her friend and from Otto to Leopold. 'Take these people away! Give me three others of my choice instead! Then I shall be free of these undeserved reproaches!' The groundlessness of the reproaches was proved for me in the dream in the most elaborate fashion. *I* was not to blame for Irma's pains, since she herself was to blame for them by refusing to accept my solution. *I* was not concerned with Irma's pains, since they were of an organic nature and quite incurable by psychological treatment. Irma's pains could be satisfactorily explained by her widowhood (cf. the trimethylamin) which *I* had no means of altering. Irma's pains had been caused by Otto giving her an incautious injection of an unsuitable drug - a thing *I* should never have done. Irma's pains were the result of an injection with a dirty needle, like my old lady's phlebitis - whereas I never did any harm with my injections. I noticed, it is true, that these explanations of Irma's pains (which agreed in exculpating me) were not entirely consistent with one another, and indeed that they were mutually exclusive. The whole plea - for the dream was nothing else - reminded one vividly of the defence put forward by the man who was charged by one of his neighbours with having given him back a borrowed kettle in a damaged condition. The defendant asserted first, that he had given it back undamaged; secondly, that the kettle had a hole in it when he borrowed it; and thirdly, that he had never borrowed a kettle from his neighbour at all. So much the better: if only a single one of these three lines of defence were to be accepted as valid, the man would have to be acquitted.

Certain other themes played a part in the dream, which were not so obviously connected with my exculpation from Irma's illness: my daughter's illness and that of my patient who bore the same name, the injurious effect of cocaine, the disorder of my patient who was travelling in Egypt, my concern about my wife's health and about that of my brother and of Dr. M., my own physical ailments, my anxiety about my absent friend who suffered from suppurative rhinitis. But when I came to consider all of these, they could all be collected into a single group of ideas and labelled, as it were, 'concern about my own and other people's health - professional conscientiousness'. I called to mind the obscure disagreeable impression I had had when Otto brought me the news of Irma's condition. This group of thoughts that played a part in the dream enabled me retrospectively to put this transient impression into words. It was as though he had said to me: 'You don't take your medical duties seriously enough. You're not conscientious; you don't carry out what you've undertaken.' Thereupon, this group of thoughts seemed to have put itself at my disposal, so that I could produce evidence of how highly conscientious I was, of how deeply I was concerned about the health of my relations, my friends and my patients. It was a noteworthy fact that this material also included some disagreeable memories, which supported my friend Otto's accusation rather than my own vindication. The material was, as one might say, impartial; but nevertheless there was an unmistakable connection between this more extensive group of thoughts which underlay the dream and the narrower subject of the dream which gave rise to the wish to be innocent of Irma's illness.

I will not pretend that I have completely uncovered the meaning of this dream or that its interpretation is without a gap. I could spend much more time over it, derive further information from it and discuss fresh problems raised by it. I myself know the points from which further trains of thought could be followed. But considerations which arise in the case of every dream of my own restrain me from pursuing my interpretative work. If anyone should feel tempted to express a hasty condemnation of my reticence, I would advise him to make the experiment of being franker than I am. For the moment I am satisfied with the achievement of this one piece of fresh knowledge. If we adopt the method of interpreting dreams which I have indicated here, we shall find that dreams really have a meaning and are far from being the expression of a fragmentary activity of the brain, as the authorities have claimed. *When the work of interpretation has been completed, we perceive that a dream is the fulfilment of a wish.*

CHAPTER III

A DREAM IS THE FULFILMENT OF A WISH

When, after passing through a narrow defile, we suddenly emerge upon a piece of high ground, where the path divides and the finest prospects open up on every side, we may pause for a moment and consider in which direction we shall first turn our steps. Such is the case with us, now that we have surmounted the first interpretation of a dream. We find ourselves in the full daylight of a sudden discovery. Dreams are not to be likened to the unregulated sounds that rise from a musical instrument struck by the blow of some external force instead of by a player's hand; they are not meaningless, they are not absurd; they do not imply that one portion of our store of ideas is asleep while another portion is beginning to wake. On the contrary, they are psychical phenomena of complete validity - fulfilments of wishes; they can be inserted into the chain of intelligible waking mental acts; they are constructed by a highly complicated activity of the mind.

But no sooner have we begun to rejoice at this discovery than we are assailed by a flood of questions. If, as we are told by dream-interpretation, a dream represents a fulfilled wish, what is the origin of the remarkable and puzzling form in which the wish-fulfilment is expressed? What alteration have the dream thoughts undergone before being changed into the manifest dream which we remember when we wake up? How does that alteration take place? What is the source of the material that has been modified into the dream? What is the source of the many peculiarities that are to be observed in the dream-thoughts - such, for instance, as the fact that they may be mutually contradictory? (Cf. the analogy of the borrowed kettle on p. 619.) Can a dream tell us anything new about our internal psychical processes? Can its content correct opinions we have held during the day?

I propose that for the moment we should leave all these questions on one side and pursue our way further along one particular path. We have learnt that a dream can represent a wish as fulfilled. Our first concern must be to enquire whether this is a universal characteristic of dreams or whether it merely happened to be the content of the particular dream (the dream of Irma's injection) which was the first that we analysed. For even if we are prepared to find that every dream has a meaning and a psychical value, the possibility must remain open of this meaning not being the same in every dream. Our first dream was the fulfilment of a wish; a second one might turn out to be a fulfilled fear; the content of a third might be a reflection; while a fourth might merely reproduce a memory. Shall we find other wishful dreams besides this one? or are there perhaps no dreams but wishful ones?

It is easy to prove that dreams often reveal themselves without any disguise as fulfilments of wishes; so that it may seem surprising that the language of dreams was not understood long ago. For instance, there is a dream that I can produce in myself as often as I like - experimentally, as it were. If I eat anchovies or olives or any other highly salted food in the evening, I develop thirst during the night which wakes me up. But my waking is preceded by a dream; and this always has the same content, namely, that I am drinking. I dream I am swallowing down water in great gulps, and it has the delicious taste that nothing can equal but a cool drink when one is parched with thirst. Then I wake up and have to have a real drink. This simple dream is occasioned by the thirst which I become aware of when I wake. The thirst gives rise to a wish to drink, and the dream shows me that wish fulfilled. In doing so it is performing a function - which it was easy to divine. I am a good sleeper and not accustomed to be woken by any physical need. If I can succeed in appeasing my thirst by *dreaming* that I am drinking, then I need not wake up in order to quench it. This, then, is a dream of convenience. Dreaming has taken the place of action, as it often does elsewhere in life. Unluckily my need for water to quench my thirst cannot be satisfied by a dream in the same way as my thirst for revenge against my friend Otto and Dr. M.; but the good intention is there in both cases. Not long ago this same dream of mine showed some modification. I had felt thirsty even before I fell asleep, and I had emptied a glass of water that stood on the table beside my bed. A few hours later during the night I had a fresh attack of thirst, and this had inconvenient results. In order to provide myself with some water I should have had to get up and fetch the glass standing on the table by my wife's bed. I therefore had an appropriate dream that my wife was giving me a drink out of a vase; this vase was an Etruscan cinerary urn which I had brought back from a journey to Italy and had since given away. But the water in it tasted so salty (evidently because of the ashes in the urn) that I woke up. It will be noticed how conveniently everything was arranged in this dream. Since its only purpose was to fulfil a wish, it could be completely egoistical. A love of comfort and convenience is not really compatible with consideration for other people. The introduction of the cinerary urn was probably yet another wish-fulfilment. I was sorry that the vase was no longer in my possession - just as the glass of water on my wife's table was out of my reach. The urn with its ashes fitted in, too, with the salty taste in my mouth which had now grown stronger and which I knew was bound to wake me.¹

¹ Weygandt (1893, 41) was aware of the occurrence of thirst dreams, for he writes: 'The sensation of thirst is perceived with greater precision than any other; it always gives rise to an idea of its being quenched. The manner in which the thirst is represented as being quenched in the dream varies, and derives its special form from some near-by memory. Another general feature in these cases is that immediately after the idea of the thirst being quenched there follows a disappointment over the small effect produced by the imaginary refreshment.' Weygandt, however, overlooks the fact that this reaction of a dream to a stimulus is one which holds good universally. Other people who are attacked by thirst in the night may wake up without having had a dream; but that is no objection to my experiment. It merely shows that they are worse sleepers than I am. - Compare in this connection Isaiah xxix, 8: 'It shall even be as when an hungry man dreameth, and, behold, he eateth; but he awaketh, and his soul is empty: or as when a thirsty man dreameth, and, behold, he drinketh; but he awaketh, and, behold, he is faint, and his soul hath appetite.'

Dreams of convenience like these were very frequent in my youth. Having made it a practice as far back as I can remember to work late into the night, I always found it difficult to wake early. I used then to have a dream of being out of bed and standing by the washing-stand; after a while I was no longer able to disguise from myself the fact that I was really still in bed, but in the meantime I had had a little more sleep. A slothful dream of this kind, which was expressed in a particularly amusing and elegant form, has been reported to me by a young medical colleague who seems to share my liking for sleep. The landlady of his lodgings in the neighbourhood of the hospital had strict instructions to wake him in time every morning but found it no easy job to carry them out. One morning sleep seemed peculiarly sweet. The landlady called through the door: 'Wake up, Herr Pepi! It's time to go to the hospital!' In response to this he had a dream that he was lying in bed in a room in the hospital, and that there was a card over the bed on which was written: 'Pepi H., medical student, age 22.' While he was dreaming, he said to himself 'As I'm already *in* the hospital, there's no need for me to go there ' - and turned over and went on sleeping. In this way he openly confessed the motive for his dream.

Here is another dream in which once again the stimulus produced its effect during actual sleep. One of my women patients, who had been obliged to undergo an operation on her jaw which had taken an unfavourable course, was ordered by her doctors to wear a cooling apparatus on the side of her face day and night. But as soon as she fell asleep she used to throw it off. One day, after she had once more thrown the apparatus on the floor, I was asked to speak to her seriously about it. 'This time I really couldn't help it', she answered. 'It was because of a dream I had in the night. I dreamt I was in a box at the opera and very much enjoying the performance. But Herr Karl Meyer was in the nursing-home and complaining bitterly of pains in his jaw. So I told myself that as I hadn't any pain I didn't need the apparatus; and I threw it away.' The dream of this poor sufferer seems almost like a concrete representation of a phrase that sometimes forces its way on to people's lips in unpleasant situations: 'I must say I could think of something more agreeable than this.' The dream gives a picture of this more agreeable thing. The Herr Karl Meyer on to whom the dreamer transplanted her pains was the most indifferent young man of her acquaintance that she could call to mind.

The wish-fulfilment can be detected equally easily in some other dreams which I have collected from normal people. A friend of mine, who knows my theory of dreams and has told his wife of it, said to me one day: 'My wife has asked me to tell you that she had a dream yesterday that she was having her period. You can guess what that means.' I could indeed guess it. The fact that this young married woman dreamt that she was having her period meant that she had missed her period. I could well believe that she would have been glad to go on enjoying her freedom a little longer before shouldering the burden of motherhood. It was a neat way of announcing her first pregnancy. Another friend of mine wrote and told me that, not long before, his wife had dreamt that she had noticed some milk stains on the front of her vest. This too was an announcement of pregnancy, but not of a first one. The young mother was wishing that she might have more nourishment to give her second child than she had had for her first.

A young woman had been cut off from society for weeks on end while she nursed her child through an infectious illness. After the child's recovery, she had a dream of being at a party at which, among others, she met Alphonse Daudet, Paul Bourget, and Marcel Prévost; they were all most affable to her and highly amusing. All of the authors resembled their portraits, except Marcel Prévost, of whom she had never seen a picture; and he looked like . . . the disinfection officer who had fumigated the sick-room the day before and who had been her first visitor for so long. Thus it seems possible to give a complete translation of the dream: 'It's about time for something more amusing than this perpetual sick-nursing.'

These examples will perhaps be enough to show that dreams which can only be understood as fulfilments of wishes and which bear their meaning upon their faces without disguise are to be found under the most frequent and various conditions. They are mostly short and simple dreams, which afford a pleasant contrast to the confused and exuberant compositions that have in the main attracted the attention of the authorities. Nevertheless, it will repay us to pause for a moment over these simple dreams. We may expect to find the very simplest forms of dreams in *children*, since there can be no doubt that their psychical productions are less complicated than those of adults. Child psychology, in my opinion, is destined to perform the same useful services for adult psychology that the investigation of the structure or development of the lower animals has performed for research into the structure of the higher classes of animals. Few deliberate efforts have hitherto been made to make use of child psychology for this purpose.

The dreams of young children are frequently pure wish-fulfilments and are in that case quite uninteresting compared with the dreams of adults. They raise no problems for solution; but on the other hand they are of inestimable importance in proving that, in their essential nature, dreams represent fulfilments of wishes. I have been able to collect a few instances of such dreams from material provided by my own children.

I have to thank an excursion which we made to the lovely village of Hallstatt in the summer of 1896 for two dreams: one of these was dreamt by my daughter, who was then eight and a half, and the other by her brother of five and a quarter. I must explain by way of preamble that we had been spending the summer on a hillside near Aussee, from which, in fine weather, we enjoyed a splendid view of the Dachstein. The Simony Hütte could be clearly distinguished through a telescope. The children made repeated attempts at seeing it through the telescope - I cannot say with what success. Before our excursion I had told the children that Hallstatt lay at the foot of the Dachstein. They very much looked forward to the day. From Hallstatt we walked up the Echerntal, which delighted the children with its succession of changing landscapes. One of them, however, the five year-old boy, gradually became fretful. Each time a new mountain came into view he asked if that was the Dachstein and I had to say 'No, only one of the foothills.' After he had asked the question several times, he fell completely silent; and he refused point-blank to come with us up the steep path to the waterfall. I thought he was tired. But next morning he came to me with a radiant face and said: 'Last night I dreamt we were at the Simony Hütte.' I understood him then. When I had spoken about the Dachstein, he had expected to climb the mountain in the course of our excursion to Hallstatt and to find himself at close quarters with the hut which there had been so much talk about in connection with the telescope. But when he found that he was being fobbed off with foothills and a waterfall, he felt disappointed and out of spirits. The dream was a compensation. I tried to discover its details, but they were scanty: 'You have to climb up steps for six hours' - which was what he had been told.

The same excursion stirred up wishes in the eight-and-a-half year-old girl as well - wishes which had to be satisfied in a dream. We had taken our neighbour's twelve-year-old son with us to Hallstatt. He was already a full-blown gallant, and there were signs that he had engaged the young lady's affections. Next morning she told me the following dream: 'Just fancy! I had a dream that Emil was one of the family and called you "Father" and "Mother" and slept with us in the big room like the boys. Then Mother came in and threw a handful of big bars of chocolate, wrapped up in blue and green paper, under our beds.' Her brothers, who have evidently not inherited a faculty for understanding dreams, followed the lead of the authorities and declared that the dream was nonsense. The girl herself defended one part of the dream at least; and it throws light on the theory of the neuroses to learn *which* part. 'Of course it's nonsense Emil being one of the family; but the part about the bars of chocolate isn't.' It had been precisely on that point that I had been in the dark, but the girl's mother now gave me the explanation. On their way home from the station the children had stopped in front of a slot-machine from which they were accustomed to obtain bars of chocolate of that very kind, wrapped in shiny metallic paper. They had wanted to get some; but their mother rightly decided that the day had already fulfilled enough wishes and left this one over to be fulfilled by the dream. I myself had not observed the incident. But the part of the dream which had been proscribed by my daughter was immediately clear to me. I myself had heard our well-behaved guest telling the children on the walk to wait till Father and Mother caught up with them. The little girl's dream turned this temporary kinship into permanent adoption. Her affection was not yet able to picture any other forms of companionship than those which were represented in the dream and which were based on her relation to her brothers. It was of course impossible to discover without questioning her why the bars of chocolate were thrown under the beds.

A friend of mine has reported a dream to me which was very much like my son's. The dreamer was an eight-year-old girl. Her father had started off with several children on a walk to Dornbach, with the idea of visiting the Rohrer Hütte. As it was getting late, however, he had turned back, promising the children to make up for the disappointment another time. On their way home they had passed the sign-post that marks the path up to the Hameau. The children had then asked to be taken up to the Hameau; but once again for the same reason they had to be consoled with the promise of another day. Next morning the eight-year-old girl came to her father and said in satisfied tones: 'Daddy, I dreamt last night that you went with us to the Rohrer Hütte and the Hameau.' In her impatience she had anticipated the fulfilment of her father's promises.

Here is an equally straightforward dream, provoked by the beauty of the scenery at Aussee in another of my daughters, who was at that time three and a quarter. She had crossed the lake for the first time, and the crossing had been too short for her: when we reached the landing-stage she had not wanted to leave the boat and had wept bitterly. Next morning she said: 'Last night I went on the lake.' Let us hope that her dream-crossing had been of a more satisfying length.

My eldest boy, then eight years old, already had dreams of his phantasies coming true: he dreamt that he was driving in a chariot with Achilles and that Diomedes was the charioteer. As may be guessed, he had been excited the day before by a book on the legends of Greece which had been given to his elder sister.

If I may include words spoken by children in their sleep under the heading of dreams, I can at this point quote one of the most youthful dreams in my whole collection. My youngest daughter, then nineteen months old, had had an attack of vomiting one morning and had consequently been kept without food all day. During the night after this day of starvation she was heard calling out excitedly in her sleep: 'Anna Fweud, stwawbewwies, wild stwawbewwies, omblet, pudden!' At that time she was in the habit of using her own name to express the idea of taking possession of something. The menu included pretty well everything that must have seemed to her to make up a desirable meal. The fact that strawberries appeared in it in two varieties was a demonstration against the domestic health regulations. It was based upon the circumstance, which she had no doubt observed, that her nurse had attributed her indisposition to a surfeit of strawberries. She was thus retaliating in her dream against this unwelcome verdict.¹

Though we think highly of the happiness of childhood because it is still innocent of sexual desires, we should not forget what a fruitful source of disappointment and renunciation, and consequently what a stimulus to dreaming, may be provided by the other of the two great vital instincts.² Here is another instance of this. My nephew, aged 22 months, had been entrusted with the duty of congratulating me on my birthday and of presenting me with a basket of cherries, which are still scarcely in season at that time of year. He seems to have found the task a hard one, for he kept on repeating 'Chewwies in it' but could not be induced to hand the present over. However, he found a means of compensation. He had been in the habit every morning of telling his mother that he had a dream of the 'white soldier' - a Guards officer in his white cloak whom he had once gazed at admiringly in the street. On the day after his birthday sacrifice he awoke with a cheerful piece of news, which could only have originated from a dream: 'Hermann eaten all the chewwies!'³

¹ The same feat was accomplished shortly afterwards by a dream produced by this little girl's grandmother - their combined ages came to some seventy years. She had been obliged to go without food for a whole day on account of a disturbance due to a floating kidney. During the following night, no doubt imagining herself back in the heyday of her girlhood, she dreamt that she had been 'asked out' to both of the principal meals and been served at both with the most appetizing delicacies.

² [Footnote added in 1911:] A closer study of the mental life of children has taught us, to be sure, that sexual instinctual forces, in infantile form, play a large enough part, and one that has been too long overlooked, in the psychical activity of children. Closer study, too, has given us grounds for feeling some doubt in regard to the happiness of childhood as it has been constructed by adults in retrospect. Cf. my *Three Essays on the Theory of Sexuality* (1905d).

³ [Footnote added 1911:] The fact should be mentioned that children soon begin to have more complicated and less transparent dreams, and that, on the other hand, adults in certain circumstances often have dreams of a similarly simple, infantile character. The wealth of unexpected material that may occur in the dreams of children of four or five is shown by examples in my 'Analysis of a Phobia in a Five-Year-Old Boy' (1909b) and in Jung (1910a). - [Added 1914:] For analytical interpretations of children's dreams see also von Hug-Hellmuth (1911 and 1913), Putnam (1912), van Raalte (1912), Spielrein (1913) and Tausk (1913). Children's dreams are also reported by Bianchieri (1912), Busemann (1909 and 1910), Doglia and Bianchieri (1910-11) and, in particular, Wiggam (1909), who laid stress on their trend towards wish-fulfilment. - [Added 1911:] On the other hand, dreams of an infantile type seem to occur in adults with special frequency when they find themselves in unusual external circumstances. Thus Otto Nordenskjöld (1904, 1, 336 f.) writes as follows of the members of his expedition while they were wintering in the Antarctic: 'The direction taken by our innermost thoughts was very clearly shown by our dreams, which were never more vivid or numerous than at this time. Even those of us who otherwise dreamt but rarely had long stories to tell in the morning when we exchanged our latest experiences in this world of the imagination. They were all concerned with the outside world which was now so remote from us, though they were often adapted to our actual circumstances. One of my companions had a particularly characteristic dream of being back in his school class-room, where it was his task to skin miniature seals which had been specially prepared for instructional purposes. Eating and drinking, however, were the pivot round which our dreams most often revolved. One of us, who had a special gift for attending large luncheon parties during the night, was proud if he was able to report in the morning that he had "got through a three-course dinner". Another of us dreamt of tobacco, of whole mountains of tobacco; while a third dreamt of a ship in full sail coming in across open water. Yet another dream is worth repeating. The postman brought round the mail and gave a long explanation of why we had had to wait so long for it: he had delivered it at the wrong address and had only succeeded in recovering it with great difficulty. We dreamt, of course, of still more impossible things. But there was a most striking lack of imaginativeness shown by almost all the dreams that I dreamt myself or heard described. It would certainly be of great psychological interest if all these dreams could be recorded. And it will easily be understood how much we longed for sleep, since it could offer each one of us everything that he most eagerly desired.' - [Added 1914:] According to Du Prel (1885, 231), 'Mungo Park, when he was almost dying of thirst on one of his African journeys, dreamt unceasingly of the well-watered valleys and meadows of his home. Similarly, Baron Trenck suffering torments of hunger while he was a prisoner in the fortress at Magdeburg, dreamt of being surrounded by sumptuous meals; and George Back, who took part in Franklin's first expedition, when he was almost dying of starvation as a result of his fearful privations, dreamt constantly and regularly of copious meals.'

I do not myself know what animals dream of. But a proverb, to which my attention was drawn by one of my students, does claim to know. 'What', asks the proverb, 'do geese dream of?' And it replies: 'Of maize.'¹ The whole theory that dreams are wish-fulfilments is contained in these two phrases.²

It will be seen that we might have arrived at our theory of the hidden meaning of dreams most rapidly merely by following linguistic usage. It is true that common language sometimes speaks of dreams with contempt. (The phrase '*Träume sind Schäume* [Dreams are froth]' seems intended to support the scientific estimate of dreams.) But, on the whole, ordinary usage treats dreams above all as the blessed fulfillers of wishes. If ever we find our expectation surpassed by the event, we exclaim in our delight: 'I should never have imagined such a thing even in my wildest dreams.'

¹ [Footnote added 1911:] A Hungarian proverb quoted by Ferenczi goes further and declares that 'pigs dream of acorns and geese dream of maize'. - [Added 1914:] A Jewish proverb runs: 'What do hens dream of? - of millet.' (Bernstein and Segel, 1908, 116.)

² [Footnote added 1914:] I am far from seeking to maintain that I am the first writer to have had the idea of deriving dreams from wishes. (Cf. the opening sentence of my next chapter.) Those who attach any importance to anticipations of this kind may go back to classical antiquity and quote Herophilus, a physician who lived under the first Ptolemy. According to Büchschütz (1868, 33), he distinguished three sorts of dreams: those which are sent by the gods, those which are natural and arise when the mind forms a picture of something that is agreeable to it and will come about, and those which are of a mixed nature and which arise of their own accord from the emergence of pictures in which we see what we wish for. J. Störcke (1913,) has drawn attention to a dream in Scherner's collection which that writer himself describes as the fulfilment of a wish. Scherner (1861, 239) writes: 'The dreamer's imagination fulfilled her waking wish so promptly, simply because that wish was emotionally active in her.' Scherner classes this dream among 'dreams of mood'; alongside it he places 'dreams of erotic yearning' in men and women, and 'dreams of ill-temper'. There is clearly no question of Scherner attributing any more importance to wishes in the instigation of dreams than to any other waking mental state: still less is there any question of his having related wishes to the essential nature of dreaming.

CHAPTER IV

DISTORTION IN DREAMS

If I proceed to put forward the assertion that the meaning of *every* dream is the fulfilment of a wish, that is to say that there cannot be any dreams but wishful dreams, I feel certain in advance that I shall meet with the most categorical contradiction.

'There is nothing new,' I shall be told, 'in the idea that *some* dreams are to be regarded as wish-fulfilments; the authorities noticed that fact long ago. Cf. Radestock (1879, 137 f.), Volkelt (1875, 110 f.), Purkinje (1846, 456), Tissié (1898, 70), Simon (1888, 42, on the hunger dreams of Baron Trenck while he was a prisoner), and a passage in Griesinger (1845, 89).¹ But to assert that there are no dreams other than wish-fulfilment dreams is only one more unjustifiable generalization, though fortunately one which it is easy to disprove. After all, plenty of dreams occur which contain the most distressing subject matter but never a sign of any wish-fulfilment. Eduard von Hartmann, the philosopher of pessimism, is probably furthest removed from the wish-fulfilment theory. In his *Philosophie des Unbewussten* (1890, 2, 344) he writes: "When it comes to dreams, we find all the annoyances of waking life carried over into the state of sleep; the only thing we do *not* find is what can to some extent reconcile an educated man to life - scientific and artistic enjoyment. . . ." But even less disgruntled observers have insisted that pain and unpleasure are more common in dreams than pleasure: for instance, Scholz (1893, 57), Volkelt (1875, 80), and others. Indeed two ladies, Florence Hallam and Sarah Weed (1896, 499), have actually given statistical expression, based on a study of their own dreams, to the preponderance of unpleasure in dreaming. They find that 57.2 per cent of dreams are "disagreeable" and only 28.6 percent positively "pleasant". And apart from these dreams, which carry over into sleep the various distressing emotions of life, there are anxiety-dreams, in which that most dreadful of all unpleasurable feelings holds us in its grasp till we awaken. And the commonest victims of these anxiety-dreams are precisely children,² whose dreams you have described as undisguised wish-fulfilments.'

¹ [Footnote added 1914:] A writer as early as Plotinus, the Neoplatonist, is quoted by Du Prel (1885, 276) as saying: 'When our desires are aroused, imagination comes along and, as it were, presents us with the objects of those desires.'

² Cf. Debacker (1881) on pavor nocturnus.

It does in fact look as though anxiety-dreams make it impossible to assert as a general proposition (based on the examples quoted in my last chapter) that dreams are wish-fulfilments; indeed they seem to stamp any such proposition as an absurdity.

Nevertheless, there is no great difficulty in meeting these apparently conclusive objections. It is only necessary to take notice of the fact that my theory is not based on a consideration of the manifest content of dreams but refers to the thoughts which are shown by the work of interpretation to lie behind dreams. We must make a contrast between the *manifest* and the *latent* content of dreams. There is no question that there are dreams whose manifest content is of the most distressing kind. But has anyone tried to interpret such dreams? to reveal the latent thoughts behind them? If not, then the two objections raised against my theory will not hold water: it still remains possible that distressing dreams and anxiety-dreams, when they have been interpreted, may turn out to be fulfilments of wishes.¹

¹ [*Footnote added 1909:*] It is hard to credit the obstinacy with which readers and critics of this book shut their eyes to this consideration and overlook the fundamental distinction between the manifest and latent content of dreams. - On the other hand, nothing in the literature of the subject comes so near to my hypothesis as a passage in James Sully's essay 'The Dream as a Revelation' (1893, 364). The fact that I am only now quoting it for the first time is no sign of disparagement: 'It would seem then, after all, that dreams are not the utter nonsense they have been said to be by such authorities as Chaucer, Shakespeare and Milton. The chaotic aggregations of our night-fancy have a significance and communicate new knowledge. Like some letter in cypher, the dream-inscription when scrutinized closely loses its first look of balderdash and takes on the aspect of a serious, intelligible message. Or, to vary the figure slightly, we may say that, like some palimpsest, the dream discloses beneath its worthless surface-characters traces of an old and precious communication.'

When in the course of a piece of scientific work we come upon a problem which is difficult to solve, it is often a good plan to take up a second problem along with the original one - just as it is easier to crack two nuts together than each separately. Thus we are not only faced by the question 'How can distressing dreams and anxiety-dreams be wish-fulfilments?'; our reflections enable us to add a second question: 'Why is it that dreams with an indifferent content, which turn out to be wish-fulfilments, do not express their meaning undisguised?' Take, for instance, the dream which I treated at such length of Irma's injection. It was not by any means of a distressing nature and interpretation showed it as a striking example of the fulfilment of a wish. But why should it have needed any interpretation at all? Why did it not say what it meant straight out? At first sight the dream of Irma's injection gave no impression that it represented a wish of the dreamer's as fulfilled. My readers will have had no such impression; but neither did I myself before I carried out the analysis. Let us describe this behaviour of dreams, which stands in so much need of explanation, as 'the phenomenon of distortion in dreams'. Thus our second problem is: what is the origin of dream-distortion?

A number of possible solutions of the problem may at once occur to us: as, for instance, that some incapacity exists during sleep for giving direct expression to our dream-thoughts. But the analysis of certain dreams forces us to adopt another explanation of distortion in dreams. I will exemplify this by another dream of my own. Once again this will involve me in a variety of indiscretions; but a thorough elucidation of the problem will compensate for my personal sacrifice.

PREAMBLE. - In the spring of 1897 I learnt that two professors at our university had recommended me for appointment as professor extraordinarius. The news surprised and greatly delighted me, since it implied recognition by two eminent men, which could not be put down to any considerations of a personal kind. But I at once warned myself not to attach any expectations to the event. During the last few years the Ministry had disregarded recommendations of that sort; and several of my colleagues who were my seniors in age and at least my equals in merit had been waiting vainly for appointment. I had no reason to believe that I should be more fortunate. I therefore determined to meet the future with resignation. So far as I knew, I was not an ambitious man; I was following my profession with gratifying success even without the advantages afforded by a title. Moreover there was no question of my pronouncing the grapes sweet or sour: they hung far too high over my head.

One evening I had a visit from a friend - one of the men whose example I had taken as a warning to me. For a considerable time he had been a candidate for promotion to a professorship, a rank which in our society turns its holder into a demi-god to his patients. Less resigned than I was, however, he was in the habit of paying his respects from time to time in the offices of the Ministry with a view to advancing his prospects. He had been paying one of these visits just before calling on me. He told me that on this occasion he had driven the exalted official into a corner and had asked straight out whether the delay over his appointment was not in fact due to denominational considerations. The reply had been that, in view of the present state of feeling, it was no doubt true that, for the moment, His Excellency was not in a position, etc. etc. 'At least I know where I am now', my friend had concluded. It was not news to me, though it was bound to strengthen my feeling of resignation; for the same denominational considerations applied to my own case.

On the morning after this visit I had the following dream, which was remarkable among other things for its form. It consisted of two thoughts and two pictures - each thought being succeeded by a picture. I shall, however, report only the first half of the dream here, since the other half has no connection with the purpose for which I am describing the dream.

I. . . . *My friend R. was my uncle. - I had a great feeling of affection for him.*

II. *I saw before me his face, somewhat changed. It was as though it had been drawn out lengthways. A yellow beard that surrounded it stood out especially clearly.*

Then followed the two other pieces which I shall pass over - once more a thought followed by a picture.

The interpretation of the dream took place as follows.

When, during the course of the morning, the dream came into my head, I laughed aloud and said: 'The dream's nonsense!' But it refused to go away and followed me about all day, till at last in the evening I began to reproach myself: 'If one of your patients who was interpreting a dream could find nothing better to say than that it was nonsense, you would take him up about it and suspect that the dream had some disagreeable story at the back of it which he wanted to avoid becoming aware of. Treat yourself in the same way. Your opinion that the dream is nonsense only means that you have an internal resistance against interpreting it. Don't let yourself be put off like this.' So I set about the interpretation.

'*R. was my uncle.*' What could that mean? I never had more than one uncle - Uncle Josef.¹ There was an unhappy story attached to him. Once - more than thirty years ago - in his eagerness to make money, he allowed himself to be involved in a transaction of a kind that is severely punished by the law, and he was in fact punished for it. My father, whose hair turned grey from grief in a few days, used always to say that Uncle Josef was not a bad man but only a simpleton; those were his words. So that if my friend R. was my Uncle Josef, what I was meaning to say was that R. was a simpleton. Hardly credible and most disagreeable! - But there was the face which I saw in the dream with its elongated features and yellow beard. My uncle did in fact have a face like that, elongated and framed in a handsome fair beard. My friend R. had originally been extremely dark; but when black-haired people begin to turn grey they pay for the splendour of their youth. Hair by hair, their black beards go through an unpleasing change of colour: first they turn to a reddish brown, then to a yellowish brown, and only then to a definite grey. My friend R.'s beard was at that time passing through this stage - and so, incidentally, was my own, as I had noticed with dissatisfaction. The face that I saw in the dream was at once my friend R.'s and my uncle's. It was like one of Galton's composite photographs. (In order to bring out family likenesses, Galton used to photograph several faces on the same plate.) So there could be no doubt that I really did mean that my friend R. was a simpleton - like my Uncle Josef.

¹ It is astonishing to observe the way in which my memory - my waking memory - was narrowed at this point, for the purposes of the analysis. Actually I have known five of my uncles and loved and honoured one of them. But at the moment at which I overcame my resistance to interpreting the dream I said to myself that I never had more than one uncle - the one that was intended in the dream.

I still had no idea at all what could be the purpose of this comparison, against which I continued to struggle. It did not go very deep, after all, since my uncle was a criminal, whereas my friend R. bore an unblemished character . . . except for having been fined for knocking a boy down with his bicycle. Could I have had that crime in mind? That would have been making fun of the comparison. At this point I remembered another conversation which I had had a few days earlier with another colleague, N., and, now I came to think of it, upon the same subject. I had met N. in the street. He too had been recommended for a professorship. He had heard of the honour that had been paid me and had offered me his congratulations on it; but I had unhesitatingly refused to accept them. 'You are the last person', I had said, 'to make that kind of joke; you know what such a recommendation is worth from your own experience.' 'Who can say?' he had answered - jokingly, it seemed; 'there was something definite against *me*. Don't you know that a woman once started legal proceedings against me? I needn't assure you that the case was dismissed. (It was a disgraceful attempt at blackmail; and I had the greatest difficulty in saving the prosecutrix from being punished. But perhaps they may be using this at the Ministry as an excuse for not appointing me. But *you* have an unblemished character.' This told me who the criminal was, and at the same time showed me how the dream was to be interpreted and what its purpose was. My Uncle Josef represented my two colleagues who had not been appointed to professorships - the one as a simpleton and the other as a criminal. I now saw too why they were represented in this light. If the appointment of my friends R. and N. had been postponed for 'denominational' reasons, my own appointment was also open to doubt; if, however, I could attribute the rejection of my two friends to other reasons, which did not apply to me, my hopes would remain untouched. This was the procedure adopted by my dream: it made one of them, R., into a simpleton and the other, N., into a criminal, whereas *I* was neither the one nor the other; thus we no longer had anything in common; I could rejoice at my appointment to a professorship, and I could avoid drawing the distressing conclusion that R.'s report of what the high official had said to him must apply equally to me.

But I felt obliged to proceed still further with my interpretation of the dream; I felt I had not yet finished dealing with it satisfactorily. I was still uneasy over the light-heartedness with which I had degraded two of my respected colleagues in order to keep open my own path to a professorship. My dissatisfaction with my conduct, however, had diminished since I had come to realize the worth that was to be attached to expressions in dreams. I was prepared to deny through thick and thin that I really considered that R. was a simpleton and that I really disbelieved N.'s account of the blackmailing affair. Nor did I believe that Irma was really made dangerously ill through being injected with Otto's preparation of propyl. In both these cases what my dreams had expressed was only *my wish that it might be so*. The assertion in which my wish was realized sounded less absurd in the later dream than in the earlier one; it made cleverer use of the actual facts in its construction, like a well designed slander of the kind that makes people feel that 'there's something in it'. For one of the professors in his own faculty had voted against my friend R., and my friend N. had himself innocently provided me with the material for my aspersions. Nevertheless, I must repeat, the dream seemed to me to stand in need of further elucidation.

I then recalled that there was still a piece of the dream which the interpretation had not touched. After the idea had occurred to me that R. was my uncle, I had had a warm feeling of affection for him in the dream. Where did that feeling belong? I had naturally never had any feeling of affection for my Uncle Josef. I had been fond of my friend R. and had esteemed him for many years; but if I had gone up to him and expressed my sentiments in terms approaching the degree of affection I had felt in the dream, there could be no doubt that he would have been astonished. My affection for him struck me as unguine and exaggerated - like the judgement of his intellectual qualities which I had expressed by fusing his personality with my uncle's, though *there* the exaggeration had been in the opposite direction. But a new light began to dawn on me. The affection in the dream did not belong to the latent content, to the thoughts that lay behind the dream; it stood in contradiction to them and was calculated to conceal the true interpretation of the dream. And probably that was precisely its *raison d'être*. I recalled my resistance against embarking on the interpretation, how long I had put it off and how I had declared that the dream was sheer nonsense. My psycho-analytic treatments taught me how a repudiation of that kind was to be interpreted: it had no value as a judgement but was simply an expression of emotion. If my little daughter did not want an apple that was offered to her, she asserted that the apple tasted sour without having tasted it. And if my patients behaved like the child, I knew that they were concerned with an idea which they wanted to repress. The same was true of my dream. I did not want to interpret it, because the interpretation contained something that I was struggling against. When I had completed the interpretation I learnt what it was that I had been struggling against - namely, the assertion that R. was a simpleton. The affection that I felt for R. could not be derived from the latent dream-thoughts; but no doubt it originated from this struggle of mine. If my dream was distorted in this respect from its latent content - and distorted into its opposite - then the affection that was manifest in the dream served the purpose of this distortion. In other words, distortion was shown in this case to be deliberate and to be a means of *dissimulation*. My dream thoughts had contained a slander against R.; and, in order that I might not notice this, what appeared in the dream was the opposite, a feeling of affection for him.

It seemed as though this might be a discovery of general validity. It is true that, as was shown by the instances quoted in Chapter III, there are some dreams which are undisguised fulfilments of wishes. But in cases where the wish-fulfilment is unrecognizable, where it has been disguised, there must have existed some inclination to put up a defence against the wish; and owing to this defence the wish was unable to express itself except in a distorted shape. I will try to seek a social parallel to this internal event in the mind. Where can we find a similar distortion of a psychical act in social life? Only where two persons are concerned, one of whom possesses a certain degree of power which the second is obliged to take into account. In such a case the second person will distort his psychical acts or, as we might put it, will dissimulate. The politeness which I practise every day is to a large extent dissimulation of this kind; and when I interpret my dreams for my readers I am obliged to adopt similar distortions. The poet complains of the need for these distortions in the words:

Das Beste, was du wissen kannst,
Darfst du den Buben doch nicht sagen.¹

A similar difficulty confronts the political writer who has disagreeable truths to tell to those in authority. If he presents them undisguised, the authorities will suppress his words - after they have been spoken, if his pronouncement was an oral one, but beforehand, if he had intended to make it in print. A writer must beware of the censorship, and on its account he must soften and distort the expression of his opinion. According to the strength and sensitiveness of the censorship he finds himself compelled either merely to refrain from certain forms of attack, or to speak in allusions in place of direct references, or he must conceal his objectionable pronouncement beneath some apparently innocent disguise: for instance, he may describe a dispute between two Mandarins in the Middle Kingdom, when the people he really has in mind are officials in his own country. The stricter the censorship, the more far-reaching will be the disguise and the more ingenious too may be the means employed for putting the reader on the scent of the true meaning.²

¹ ['After all, the best of what you know may not be told to boys.']

² [Footnote added 1919:] Frau Dr. H. von Hug-Hellmuth (1915) has recorded a dream which is perhaps better fitted than any to justify my choice of nomenclature. In this example the dream-distortion adopted the same methods as the postal censorship for expunging passages which were objectionable to it. The postal censorship makes such passages unreadable by blacking them out; the dream-censorship replaced them by an incomprehensible mumble.

In order to make the dream intelligible, I must explain that the dreamer, a cultivated and highly esteemed lady, was fifty years of age. She was the widow of an officer of high rank who had died some twelve years previously and was the mother of grown sons, one of whom was in the field at the time of the dream.

Here then is the dream - which deals with 'love services' in war-time. 'The patient went to Garrison Hospital No. 1 and informed the sentry at the gate that she must speak to the Chief Medical Officer (mentioning a name that was unknown to her) as she wanted to volunteer for service at the hospital. She pronounced the word "service" in such a way that the N.C.O. at once understood that she meant "love service". Since she was an elderly lady, after some hesitation he allowed her to pass. Instead of finding the Chief Medical Officer, however, she reached a large and gloomy apartment in which a number of officers and army doctors were standing and sitting round a long table. She approached a staff surgeon with her request, and he understood her meaning after she had said only a few words. The actual wording of her speech in the dream was: "I and many other women and girls in Vienna are ready to . . ." at this point in the dream her words turned into a mumble " . . . for the troops - officers and other ranks without distinction." She could tell from the expressions on the officers' faces, partly embarrassed and partly sly, that everyone had understood her meaning correctly. The lady went on: "I'm aware that our decision must sound surprising, but we mean it in bitter earnest. No one asks a soldier in the field whether he wishes to die or not." There followed an awkward silence of some minutes. The staff surgeon then put his arm round her waist and said: "Suppose, madam, it actually came to . . . (mumble)." She drew away from him, thinking to herself: "He's like all the rest of them", and replied: "Good gracious, I'm an old woman and I might never come to that. Besides, there's one condition that must be observed: age must be respected. It must never happen that an elderly woman . . . (mumble) . . . a mere boy. That would be terrible." "I understand perfectly," replied the staff surgeon. Some of the officers, and among them one who had been a suitor of hers in her youth, laughed out loud. The lady then asked to be taken to the Chief Medical Officer, with whom she was acquainted, so that the whole matter could be thrashed out; but she found, to her consternation, that she could not recall his name. Nevertheless, the staff surgeon, most politely and respectfully, showed her the way up to the second floor by a very narrow, iron, spiral staircase, which led directly from the room to the upper storeys of the building. As she went up she heard an officer say: "That's a tremendous decision to make - no matter whether a woman's young or old! Splendid of her!" Feeling simply that she was doing her duty, she walked up an interminable staircase. The dream was repeated twice in the course of a few weeks, with, as the lady remarked, some quite unimportant and meaningless modifications.'

The fact that the phenomena of censorship and of dream-distortion correspond down to their smallest details justifies us in presuming that they are similarly determined. We may therefore suppose that dreams are given their shape in individual human beings by the operation of two psychical forces (or we may describe them as currents or systems); and that one of these forces constructs the wish which is expressed by the dream, while the other exercises a censorship upon this dream-wish and, by the use of that censorship, forcibly brings about a distortion in the expression of the wish. It remains to enquire as to the nature of the power enjoyed by this second agency which enables it to exercise its censorship. When we bear in mind that the latent dream-thoughts are not conscious before an analysis has been carried out, whereas the manifest content of the dream is consciously remembered, it seems plausible to suppose that the privilege enjoyed by the second agency is that of permitting thoughts to enter consciousness. Nothing, it would seem, can reach consciousness from the first system without passing the second agency; and the second agency allows nothing to pass without exercising its rights and making such modifications as it thinks fit in the thought which is seeking admission to consciousness. Incidentally, this enables us to form a quite definite view of the 'essential nature' of consciousness: we see the process of a thing becoming conscious as a specific psychical act, distinct from and independent of the process of the formation of a presentation or idea; and we regard consciousness as a sense organ which perceives data that arise elsewhere. It can be demonstrated that these basic assumptions are absolutely indispensable to psychopathology. We must, however, postpone our further consideration of them to a later stage.

If this picture of the two psychical agencies and their relation to consciousness is accepted, there is a complete analogy in political life to the extraordinary affection which I felt in my dream for my friend R., who was treated with such contumely during the dream's interpretation. Let us imagine a society in which a struggle is in process between a ruler who is jealous of his power and an alert public opinion. The people are in revolt against an unpopular official and demand his dismissal. But the autocrat, to show that he need take no heed of the popular wish, chooses that moment for bestowing a high distinction upon the official, though there is no other reason for doing so. In just the same way my second agency, which commands the approaches to consciousness, distinguished my friend R. by a display of excessive affection simply because the wishful impulses belonging to the first system, for particular reasons of their own on which they were intent at the moment, chose to condemn him as a simpleton.¹

¹ [*Footnote added 1911:*] Hypocritical dreams of this description are not uncommon events in my own case or in that of other people. While I was engaged in working out a certain scientific problem, I was troubled for several nights in close succession by a somewhat confusing dream which had as its subject a reconciliation with a friend whom I had dropped many years before. On the fourth or fifth occasion I at last succeeded in understanding the meaning of the dream. It was an incitement to abandon my last remnants of consideration for the person in question and to free myself from him completely, and it had been hypocritically disguised as its opposite. I have reported elsewhere a 'hypocritical Oedipus dream', dreamt by a man, in which the hostile impulses and death-wishes contained in the dream-thoughts were replaced by manifest affection. Another kind of hypocritical dream will be mentioned below in Chapter VI.

These considerations may lead us to feel that the interpretation of dreams may enable us to draw conclusions as to the structure of our mental apparatus which we have hoped for in vain from philosophy. I do not propose, however, to follow this line of thought; but, having cleared up the matter of distortion in dreams, I shall go back to the problem from which we started. The question raised was how dreams with a distressing content can be resolved into wish-fulfilments. We now see that this is possible if dream-distortion has occurred and if the distressing content serves only to disguise something that is wished for. Bearing in mind our assumption of the existence of two psychical agencies, we can further say that distressing dreams do in fact contain something which is distressing to the *second* agency, but something which at the same time fulfils a wish on the part of the *first* agency. They are wishful dreams in so far as every dream arises from the first agency; the relation of the second agency towards dreams is of a *defensive* and not of a *creative* kind.¹ If we were to restrict ourselves to considering what the second agency contributes to dreams, we could never arrive at an understanding of them: all the conundrums which the authorities have observed in dreams would remain unsolved.

The fact that dreams really have a secret meaning which represents the fulfilment of a wish must be proved afresh in each particular case by analysis. I shall therefore select a few dreams with a distressing content and attempt to analyse them. Some of them are the dreams of hysterical patients which require lengthy preambles and an occasional excursus into the psychical processes characteristic of hysteria. But I cannot escape this aggravation of the difficulties of presenting my argument.

As I have already explained, when I undertake the analytic treatment of a psycho-neurotic patient his dreams are invariably discussed between us. In the course of these discussions I am obliged to give him all the psychological explanations which have enabled me myself to reach an understanding of his symptoms. I am thereupon subjected to a remorseless criticism, certainly no less severe than I have to expect from the members of my own profession. And my patients invariably contradict my assertion that all dreams are fulfilments of wishes. Here, then, are some instances from the material of dreams that have been brought up against me as evidence to the contrary.

¹ [Footnote added 1930:] Later we shall also come across instance in which, on the contrary, a dream expresses a wish on the part of the *second* agency.

'You're always saying to me', began a clever woman patient of mine, 'that a dream is a fulfilled wish. Well, I'll tell you a dream whose subject was the exact opposite - a dream in which one of my wishes was *not* fulfilled. How do you fit that in with your theory? This was the dream:

'I wanted to give a supper-party, but I had nothing in the house but a little smoked salmon. I thought I would go out and buy something, but remembered then that it was Sunday afternoon and all the shops would be shut. Next I tried to ring up some caterers, but the telephone was out of order. So I had to abandon my wish to give a supper-party.'

I answered, of course, that analysis was the only way of deciding on the meaning of the dream; though I admitted that at first sight it seemed sensible and coherent and looked like the reverse of a wish-fulfilment. 'But what material did the dream arise from? As you know, the instigation to a dream is always to be found in the events of the previous day.'

ANALYSIS. - My patient's husband, an honest and capable wholesale butcher, had remarked to her the day before that he was getting too stout and therefore intended to start on a course of weight-reduction. He proposed to rise early, do physical exercises, keep to a strict diet, and above all accept no more invitations to supper. -She laughingly added that her husband, at the place where he regularly lunched, had made the acquaintance of a painter, who had pressed him to be allowed to paint his portrait, as he had never seen such expressive features. Her husband however had replied in his blunt manner that he was much obliged, but he was sure the painter would prefer a piece of a pretty young girl's behind to the whole of his face.¹ She was very much in love with her husband now and teased him a lot. She had begged him, too, not to give her any caviare.

I asked her what that meant; and she explained that she had wished for a long time that she could have a caviare sandwich every morning but had grudged the expense. Of course her husband would have let her have it at once if she had asked him. But, on the contrary, she had asked him *not* to give her any caviare, so that she could go on teasing him about it.

¹ Cf. the phrase 'sitting for one's portrait' and Goethe's lines:

Und wenn er keinen Hintern hat,
Wie mag der Edle sitzen?

[And if he hasn't a behind,
How can his Lordship sit?]

This explanation struck me as unconvincing. Inadequate reasons like this usually conceal unconfessed motives. They remind one of Bernheim's hypnotized patients. When one of these carries out a post-hypnotic suggestion and is asked why he is acting in this way, instead of saying that he has no idea he feels compelled to invent some obviously unsatisfactory reason. The same was no doubt true of my patient and the caviare. I saw that she was obliged to create an unfulfilled wish for herself in her actual life; and the dream represented this renunciation as having been put into effect. But why was it that she stood in need of an unfulfilled wish?

The associations which she had so far produced had not been sufficient to interpret the dream. I pressed her for some more. After a short pause, such as would correspond to the over coming of a resistance, she went on to tell me that the day before she had visited a woman friend of whom she confessed she felt jealous because her (my patient's) husband was constantly singing her praises. Fortunately this friend of hers is very skinny and thin and her husband admires a plumper figure. I asked her what she had talked about to her thing friend. Naturally, she replied, of that lady's wish to grow a little stouter. Her friend had enquired, too: 'When are you going to ask us to another meal? You always feed one so well.'

The meaning of the dream was now clear, and I was able to say to my patient: 'It is just as though when she made this suggestion you said to yourself: "A likely thing! I'm to ask you to come and eat in my house so that you may get stout and attract my husband still more! I'd rather never give another supper-party." What the dream was saying to you was that you were unable to give any supper-parties, and it was thus fulfilling your wish not to help your friend to grow plumper. The fact that what people eat at parties makes them stout had been brought home to you by your husband's decision not to accept any more invitations to supper in the interests of his plan to reduce his weight.' All that was now lacking was some coincidence to confirm the solution. The smoked salmon in the dream had not yet been accounted for. 'How', I asked, 'did you arrive at the salmon that came into your dream?' 'Oh', she replied, 'smoked salmon is my friend's favourite dish.' I happen to be acquainted with the lady in question myself, and I can confirm the fact that she grudges herself salmon no less than my patient grudges herself caviare.

The same dream admits of another and subtler interpretation, which in fact becomes unavoidable if we take a subsidiary detail into account. (The two interpretations are not mutually contradictory, but both cover the same ground; they are a good instance of the fact that dreams, like all other psychopathological structures, regularly have more than one meaning.) My patient, it will be remembered, at the same time as she was occupied with her dream of the renunciation of a wish, was also trying to bring about a renounced wish (for the caviare sandwich) in real life. Her friend had also given expression to a wish - to become stouter - and it would not have been surprising if my patient had dreamt that her friend's wish was unfulfilled; for my patient's own wish was that her friend's wish (to put on weight) should not be fulfilled. But instead of this she dreamt that one of her *own* wishes was not fulfilled. Thus the dream will acquire a new interpretation if we suppose that the person indicated in the dream was not herself but her friend, that she had put herself in her friend's place, or, as we might say, that she had 'identified' herself with her friend. I believe she had in fact done this; and the circumstance of her having brought about a renounced wish in real life was evidence of this identification.

What is the meaning of hysterical identification? It requires a somewhat lengthy explanation. Identification is a highly important factor in the mechanism of hysterical symptoms. It enables patients to express in their symptoms not only their own experiences but those of a large number of other people; it enables them, as it were, to suffer on behalf of a whole crowd of people and to act all the parts in a play single-handed. I shall be told that this is not more than the familiar hysterical imitation, the capacity of hysterics to imitate any symptoms in other people that may have struck their attention - sympathy, as it were, intensified to the point of reproduction. This, however, does no more than show us the path along which the psychological process in hysterical imitation proceeds. The path is something different from the mental act which proceeds along it. The latter is a little more complicated than the common picture of hysterical imitation; it consists in the unconscious drawing of an inference, as an example will make clear. Supposing a physician is treating a woman patient, who is subject to a particular kind of spasm, in a hospital ward among a number of other patients. He will show no surprise if he finds one morning that this particular kind of hysterical attack has found imitators. He will merely say: 'The other patients have seen it and copied it; it's a case of psychical infection.' That is true; but the psychical infection has occurred along some such lines as these. As a rule, patients know more about one another than the doctor does about any of them; and after the doctor's visit is over they turn their attention to one another. Let us imagine that this patient had her attack on a particular day; then the others will quickly discover that it was caused by a letter from home, the revival of some unhappy love-affair, or some such thing. Their sympathy is aroused and they draw the following inference, though it fails to penetrate into consciousness: 'If a cause like this can produce an attack like this, I may have the same kind of attack since I have the same grounds for having it.' If this inference were capable of entering consciousness, it might possibly give rise to a *fear* of having the same kind of attack. But in fact the inference is made in a different psychological region, and consequently results in the actual realization of the dreaded symptom. Thus identification is not simple imitation but *assimilation* on the basis of a similar aetiological pretension; it expresses a resemblance and is derived from a common element which remains in the unconscious.

Identification is most frequently used in hysteria to express a common *sexual* element. A hysterical woman identifies herself in her symptoms most readily - though not exclusively - with people with whom she has had sexual relations or with people who have had sexual relations with the same people as herself. Linguistic usage takes this into account, for two lovers are spoken of as being 'one'. In hysterical phantasies, just as in dreams, it is enough for purposes of identification that the subject should have *thoughts* of sexual relations without their having necessarily taken place in reality. Thus the patient whose dream I have been discussing was merely following the rules of hysterical processes of thought in expressing her jealousy of her friend (which incidentally she herself knew was unjustified) by taking her place in the dream and identifying herself with her by creating a symptom - the renounced wish. The process might be expressed verbally thus: my patient put herself in her friend's place in the dream because her friend was taking my patient's place with her husband and because she (my patient) wanted to take her friend's place in her husband's high opinion.¹

¹ I myself regret the insertion into my argument of excerpts from the psychopathology of hysteria. Their fragmentary presentation and detachment from their context cannot fail to detract from their enlightening effect. If, however, they serve to indicate the intimate connection between the topic of dreams and that of the psychoneuroses, they will have fulfilled the purpose for which they are inserted.

A contradiction to my theory of dreams produced by another of my women patients (the cleverest of all my dreamers) was resolved more simply, but upon the same pattern: namely that the non-fulfilment of one wish meant the fulfilment of another. One day I had been explaining to her that dreams are fulfilments of wishes. Next day she brought me a dream in which she was travelling down with her mother-in-law to the place in the country where they were to spend their holidays together. Now I knew that she had violently rebelled against the idea of spending the summer near her mother-in-law and that a few days earlier she had successfully avoided the propinquity she dreaded by engaging rooms in a far distant resort. And now her dream had undone the solution she had wished for: was not this the sharpest possible contradiction of my theory that in dreams wishes are fulfilled? No doubt; and it was only necessary to follow the dream's logical consequence in order to arrive at its interpretation. The dream showed that I was wrong. *Thus it was her wish that I might be wrong, and her dream showed that wish fulfilled.* But her wish that I might be wrong, which was fulfilled in connection with her summer holidays, related in fact to another and more serious matter. For at about the same time I had inferred from the material produced in her analysis that at a particular period of her life something must have occurred that was of importance in determining her illness. She had disputed this, since she had no recollection of it; but soon afterwards it had turned out that I was right. Thus her wish that I might be wrong, which was transformed into her dream of spending her holidays with her mother-in-law, corresponded to a well-justified wish that the events of which she was then becoming aware for the first time might never have occurred.

I have ventured to interpret - without any analysis, but only by a guess - a small episode which occurred to a friend of mine who was in the same class as I was all through our career at a secondary school. One day he listened to a lecture which I gave before a small audience on the novel idea that dreams were wish-fulfilments. He went home and dreamt that *he had lost all his cases* (he was a barrister) and afterwards arraigned me on the subject. I evaded the issue by telling him that after all one can't win *all* one's cases. But to myself I thought: 'Considering that for eight whole years I sat on the front bench as top of the class while he drifted about somewhere in the middle, he can hardly fail to nourish a wish, left over from his school-days, that some day or other I may come a complete cropper.'

A dream of a gloomier kind was also brought up against me by a patient as an objection to the theory of wishful dreams.

The patient, who was a young girl, began thus: 'As you will remember, my sister has only one boy left now - Karl; she lost his elder brother, Otto, while I was still living with her. Otto was my favourite; I more or less brought him up. I'm fond of the little one too, but of course not nearly so fond as I was of the one who died. Last night, then, I dreamt that *I saw Karl lying before me dead. He was lying in his little coffin with his hands folded and with candles all around - in fact just like little Otto, whose death was such a blow to me.* Now tell me, what can that mean? You know me. Am I such a wicked person that I can wish my sister to lose the one child she still has? Or does the dream mean that I would rather Karl were dead than Otto whom I was so much fonder of?

I assured her that this last interpretation was out of question. And after reflecting a little I was able to give her the correct interpretation of the dream, which she afterwards confirmed. I was able to do so because I was familiar with the whole of the dreamer's previous history.

The girl had early been left an orphan and had been brought up in the house of a much older sister. Among the friends who visited at the house was a man who made a lasting impression on her heart. For a time it had seemed as though her scarcely acknowledged relations with him would lead to marriage; but this happy outcome was brought to nothing by her sister, whose motives were never fully explained. After the breach the man ceased to visit the house; and shortly after the death of little Otto, on to whom she had meanwhile turned her affection, my patient herself set up on her own. She did not succeed, however, in freeing herself from her attachment to her sister's friend. Her pride bade her avoid him; but she was unable to transfer her love to any of the other admirers who presented themselves later. Whenever it was announced that the object of her affections, who was by profession a literary man, was to give a lecture anywhere, she was invariably in the audience; and she took every possible opportunity of seeing him from a distance on neutral ground. I remembered that she had told me the day before that the Professor was going to a particular concert and that she intended to go to it as well so as to enjoy a glimpse of him once more. That had been on the day before the dream, and the concert was to take place on the day on which she told me the dream. It was therefore easy for me to construct the correct interpretation, and I asked her whether she could think of anything that happened after little Otto's death. She answered at once: 'Of course! the Professor came to see us again after a long absence, and I saw him once more beside little Otto's coffin.' This was exactly what I had expected, and I interpreted the dream in this way: 'If now the other boy were to die, the same thing would happen. You would spend the day with your sister and the Professor would be certain to come to offer his condolences, so that you would see him again under the same conditions as the other time. The dream means no more than your wish to see him once more, a wish which you are inwardly struggling against. I know you have a ticket for to-day's concert in your pocket. Your dream was a dream of impatience: it anticipated the glimpse you are to have of him to-day by a few hours.'

In order to conceal her wish, she had evidently chosen a situation in which such wishes are usually suppressed, a situation in which one is so much filled with grief that one has no thought of love. Yet it is quite possible that even in the real situation of which the dream was an exact replica, beside the coffin of the elder boy whom she had loved still more, she may have been unable to suppress her tender feelings for the visitor who had been absent so long.

A similar dream of another woman patient had a different explanation. When she was young she had been remarkable for her ready wit and cheerful disposition; and these characteristics were still to be seen, at all events in the ideas that occurred to her during the treatment. In the course of a longish dream, this lady imagined that she saw her only, fifteen-year-old daughter lying dead 'in a case.' She had half a mind to use the scene as an objection to the wish-fulfilment theory, though she herself suspected that the detail of the 'case' must point the way to another view of the dream.¹ In the course of the analysis she recalled that at a party the evening before there had been some talk about the English word 'box' and the various ways in which it could be translated into German - such as '*Schachtel*', '*Loge*', '*Kasten*', '*Ohrfeige*', and so on. Other portions of the same dream enabled us to discover further that she had guessed that the English 'box' was related to the German '*Büchse*', and that she had then been plagued by a recollection that '*Büchse*' is used as a vulgar term for the female genitals. If some allowance was made for the limits of her knowledge of topographical anatomy, it might be presumed, therefore, that the child lying in the case meant an embryo in the womb. After being enlightened up to this point, she no longer denied that the dream-picture corresponded to a wish of hers. Like so many young married women, she had been far from pleased when she became pregnant; and more than once she had allowed herself to wish that the child in her womb might die. Indeed, in a fit of rage after a violent scene with her husband, she had beaten with her fists on her body so as to hit the child inside it. Thus the dead child was in fact the fulfilment of a wish, but of a wish that had been put aside fifteen years earlier. It is scarcely to be wondered at if a wish that was fulfilled after such a long delay was not recognized. Too much had changed in the interval.

¹ Like the smoked salmon in the dream of the abandoned supper party.

I shall have to return to the group of dreams to which the last two examples belong (dreams dealing with the death of relatives of whom the dreamer is fond) when I come to consider 'typical' dreams. I shall then be able to show from further instances that, in spite of their unwished for contents, all such dreams must be interpreted as wish-fulfilments.

I owe the following dream, not to a patient, but to an intelligent jurist of my acquaintance. He told it to me, once again, in order to restrain me from rash generalizing on the theory of wishful dreams. 'I dreamt', said my informant, *'that I came up to my house with a lady on my arm. A closed carriage was standing in front of it and a man came up to me, showed me his credentials as a police officer and requested me to follow him. I asked him to allow me a little time to put my affairs in order. Can you suppose that I have a wish to be arrested?'* - Of course not, I could only agree. Do you happen to know the charge on which you were arrested? - 'Yes, for infanticide, I believe.' - Infanticide? But surely you're aware that that's a crime that can only be committed by a mother on a new-born child? - 'Quite true.'¹ - And what were the circumstances in which you had the dream? What happened on the previous evening? - 'I would prefer not to tell you. It's a delicate matter.' - Nevertheless I shall have to hear it; otherwise we shall have to give up the idea of interpreting the dream. - 'Very well then, listen. I didn't spend last night at home but with a lady who means a great deal to me. When we woke up in the morning there was a further passage between us, after which I went to sleep again and had the dream I described to you.' - Is she a married woman? - 'Yes.' - And you don't want to have a child by her? - 'Oh, no; that might give us away.' - So you don't practice normal intercourse? - 'I take the precaution of withdrawing before ejaculation.' - I think I may assume that you had used this device several times during the night, and that after repeating it in the morning you felt a little uncertain whether you had carried it out success fully. - 'That's possible, no doubt.' - In that case your dream was the fulfilment of a wish. It gave you a reassurance that you had not procreated a child, or, what amounts to the same thing, that you had killed a child. The intermediate links are easily indicated. You remember that a few days ago we were talking about marriage difficulties and how inconsistent it is that there should be no objection to carrying out intercourse in such a way that no fertilization takes place, whereas any interference when once the ovum and semen have come together and a foetus has been formed is punished as a crime. We went on to recall the mediaeval controversy over the exact point of time at which the soul enters the foetus, since it is not until after that that the concept of murder becomes applicable. No doubt, too, you know Lenau's gruesome poem in which child murder and child prevention are equated. - 'Oddly enough I happened to think of Lenau this morning, quite by chance, as it seemed.' - An after-echo of your dream. And now I can show you another incidental wish-fulfilment contained in your dream. You came up to your house with the lady on your arm. Thus you were bringing her home, instead of spending the night in her house as you did in reality. There may be more than one reason why the wish-fulfilment which constitutes the core of the dream was disguised in such a disagreeable form. Perhaps you have learned from my paper on the aetiology of anxiety neurosis that I regard *coitus interruptus* as one of the aetiological factors in the development of neurotic anxiety? It would tally with this if, after carrying out sexual intercourse in this way several times, you were left in an uneasy mood which afterwards became an element in the construction of your dream. Moreover, you made use of this moodiness to help disguise the wish-fulfilment. Incidentally, your reference to infanticide has not been explained. How did you come to light on this specifically feminine crime? - 'I must admit that some years ago I became involved in an occurrence of that kind. I was responsible for a girl's trying to avoid the consequence of a love-affair with me by means of an abortion. I had nothing to do with her carrying out her intention, but for a long time I naturally felt very nervous in case the business came out.' - I quite understand that. This recollection provides a second reason why you must have been worried by your suspicion that your device might have gone wrong.

¹ It often happens that the account first given of a dream is incomplete and that the memory of the omitted portions only emerges in the course of analysis. These subsequently added portions regularly turn out to provide the key to the dream's interpretation. Cf. the discussion below on the forgetting of dreams.

A young physician who heard me describe this dream during a course of lectures must have been greatly struck by it, for he promptly re-dreamt it, applying the same pattern of thought to another theme. The day before, he had sent in his income tax return, which he had filled in perfectly honestly, since he had very little to declare. He then had a dream that *an acquaintance of his had come to him from a meeting of the tax commissioners and informed him that, while no objection had been raised to any of the other tax returns, general suspicion had been aroused by his and a heavy fine had been imposed on him.* The dream was a poorly disguised fulfilment of his wish to be known as a doctor with a large income. It recalls the well-known story of the girl who was advised not to accept a suitor because he had a violent temper and would be sure to beat her if they were married. 'If only he'd begun beating me already!' the girl replied. Her wish to be married was so intense that she was ready to take the threatened unpleasantness into the bargain, and even went so far as to turn it into a wish.

The very frequent dreams, which appear to stand in contradiction to my theory because their subject-matter is the frustration of a wish or the occurrence of something clearly unwished-for, may be brought together under the heading of 'counter-wish dreams'. If these dreams are considered as a whole, it seems to me possible to trace them back to two principles; I have not yet mentioned one of these, although it plays a large part not only in people's dreams but in their lives as well. One of the two motive forces leading to such dreams is the wish that I may be wrong. These dreams appear regularly in the course of my treatments when a patient is in a state of resistance to me; and I can count almost certainly on provoking one of them after I have explained to a patient for the first time my theory that dreams are fulfilments of wishes.¹ Indeed, it is to be expected that the same thing will happen to some of the readers of the present book: they will be quite ready to have one of their wishes frustrated in a dream if only their wish that I may be wrong can be fulfilled.

¹ [Footnote added 1911:] During the last few years similar 'counter-wish dreams' have repeatedly been reported to me by people who have heard me lecturing, as a reaction to first making the acquaintance of my 'wishful' theory of dreams.

The same point is illustrated by one last dream of the kind which I will quote from a patient under treatment. This was the dream of a girl who had succeeded in her struggle to continue her treatment with me against the will of her relatives and of the authorities whose opinions had been consulted. *She dreamt that her people forbade her to go on coming to me. She then reminded me of a promise I had given her that if necessary I would continue the treatment without a fee. To this I replied: 'I cannot make any allowances in money matters.'* It must be admitted that it was not easy to point to the wish-fulfilment in this instance. But in all such cases one discovers a second riddle, the solution of which helps one to solve the original one. What was the origin of the words she put into my mouth? Of course I had said nothing of the kind to her; but one of her brothers, and the one by whom she was most influenced, had been good enough to attribute this sentiment to me. The dream was thus intended to prove her brother right. And it was not only in her dreams that she insisted on his being right; the same idea dominated her whole life and it was the motive of her illness.

A dream which seems at first sight to put special difficulties in the way of the wish-fulfilment theory was dreamt and interpreted by a physician, and reported by August Stürcke (1911): *'I saw upon my left index-finger the first indication of syphilis on the terminal phalange.'* The reflection that, apart from the dream's unwished-for content, it appears to be clear and coherent, might dissuade us from analysing it. If, however, we are prepared to face the trouble involved, we shall find that *'Primäraffekt'* was equivalent to a *'prima affectio'* (a first love), and that the repellent ulcer turned out, to quote Stürcke's words, to 'stand for wish-fulfilments that were highly charged with emotion'.

The second motive for counter-wish dreams is so obvious that it is easy to overlook it, as I did myself for some considerable time. There is a masochistic component in the sexual constitution of many people, which arises from the reversal of an aggressive, sadistic component into its opposite. Those who find their pleasure, not in having *physical* pain inflicted on them, but in humiliation and mental torture, may be described as 'mental masochists'. It will at once be seen that people of this kind can have counter-wish dreams and unpleasurable dreams, which are none the less wish-fulfilments since they satisfy their masochistic inclinations. I will quote one such dream, produced by a young man who in his earlier years had greatly tormented his elder brother, to whom he had a homosexual attachment. His character having undergone a fundamental change, he had the following dream, which was in three pieces: *I. His elder brother was chaffing him. II. Two grown men were caressing each other with a homosexual purpose. III. His brother had sold the business of which he himself had looked forward to becoming the director.* He awoke from the last dream with the most distressing feelings. Nevertheless it was a masochistic wishful dream, and might be translated thus: 'It would serve me right if my brother were to confront me with this sale as a punishment for all the torments he had to put up with from me.'

I hope that the foregoing examples will be enough (till the next objection is raised) to make it seem plausible that even dreams with a distressing content are to be construed as wish-fulfilments. Nor will anyone regard it as a chance coincidence that the interpretation of these dreams has brought us up each time against topics about which people are loth to speak or to think. The distressing feeling aroused by these dreams is no doubt identical with the repugnance which tends (usually with success) to restrain us from discussing or mentioning such topics, and which each of us has to overcome if we nevertheless find ourselves compelled to embark on them. But the unpleasurable feeling which thus recurs in dreams does not disprove the existence of a wish. Everyone has wishes that he would prefer not to disclose to other people, and wishes that he will not admit even to himself. On the other hand, we are justified in linking the unpleasurable character of all these dreams with the fact of dream-distortion. And we are justified in concluding that these dreams are distorted and the wish-fulfilment contained in them disguised to the point of being unrecognizable precisely owing to the repugnance felt for the topic of the dream or for the wish derived from it and to an intention to repress them. The distortion in the dream is thus shown in fact to be an act of the censorship. We shall be taking into account everything that has been brought to light by our analysis of unpleasurable dreams if we make the following modification in the formula in which we have sought to express the nature of dreams: *a dream is a (disguised) fulfilment of a (suppressed or repressed) wish.*¹

¹ [Footnote added 1914:] A great living writer, who, as I have been told, refuses to hear anything of psycho-analysis or the interpretation of dreams, has independently arrived at an almost identical formula for the nature of dreams. He speaks of a dream as 'the unauthorized emergence of suppressed desires and wishes, under false features and name'. (Spitteler, 1914, 1.)

[Added 1911:] I shall anticipate questions which will be discussed later by quoting at this point Otto Rank's enlargement and modification of the above basic formula: 'On the basis and with the help of repressed, infantile sexual material, dreams regularly represent present-day, and also as a rule erotic, wishes as fulfilled, in a veiled and symbolically disguised shape.' (Rank, 1910.)

[Added 1925:] I have nowhere stated that I adopted Rank's formula as my own. The shorter version, as stated in the text above, seems to me adequate. But the mere fact of my having mentioned Rank's modification has been enough to unleash countless accusations against psycho-analysis of having asserted that 'all dreams have a sexual content'.

If this sentence is taken in the sense in which it was intended, it merely shows the unconscientious manner in which critics are accustomed to perform their functions, and the readiness with which opponents overlook the clearest statements if they do not give scope to their aggressive inclinations. For only a few pages earlier I had mentioned the variety of the wishes whose fulfilments are to be found in children's dreams (wishes to take part in an excursion or a sail on a lake, or to make up for a missed meal, and so on); and in other passages I had discussed dreams of hunger, dreams stimulated by thirst or by excretory needs, and dreams of mere convenience. Even Rank himself made no absolute assertion. The words he used were 'also as a *rule* erotic wishes', and what he said can be amply confirmed in the dreams of most adults.

The situation would be different if 'sexual' was being used by my critics in the sense in which it is now commonly employed in psycho-analysis - in the sense of 'Eros'. But my opponents are scarcely likely to have had in mind the interesting problem of whether all dreams are created by 'libidinal' instinctual forces as contrasted with 'destructive' ones.

There remain to be discussed anxiety-dreams as a special sub-species of dreams with a distressing content. The notion of regarding these as wishful dreams will meet with very little sympathy from the unenlightened. Nevertheless I can deal with anxiety-dreams very briefly at this point. They do not present us with a new aspect of the dream-problem; what they face us with is the whole question of neurotic anxiety. The anxiety that we feel in a dream is only *apparently* explained by the dream's content. If we submit the content of the dream to analysis, we find that the anxiety in the dream is no better justified by the dream's content than, let us say, the anxiety in a phobia is justified by the idea to which the phobia relates. No doubt it is true, for instance, that it is possible to fall out of a window and that there is therefore reason for exercising a certain degree of caution in the neighbourhood of a window; but we cannot see why the anxiety felt in a phobia on this subject is so great and pursues the patient far beyond its occasion. We find then that the same thing may be validly asserted both of phobias and of anxiety-dreams: in both cases the anxiety is only superficially attached to the idea that accompanies it; it originates from another source.

Since this intimate connection exists between anxiety in dreams and in neuroses, in discussing the former I must refer to the latter. In a short paper on anxiety-neurosis (Freud, 1895*b*), I argued some time ago that neurotic anxiety is derived from sexual life and corresponds to libido which has been diverted from its purpose and has found no employment. Since then this formula has met the test of time; and it enables us now to infer from it that anxiety-dreams are dreams with a sexual content, the libido belonging to which has been transformed into anxiety. There will be an opportunity later to support this assertion by the analysis of some neurotic patients' dreams. In the course, too, of a further attempt to arrive at a theory of dreams, I shall have occasion to discuss once more the determinants of anxiety-dreams and their compatibility with the theory of wish-fulfilment.

CHAPTER V

THE MATERIAL AND SOURCES OF DREAMS

When the analysis of the dream of Irma's injection showed us that a dream could be the fulfilment of a wish, our interest was at first wholly absorbed by the question of whether we had come upon a universal characteristic of dreams, and for the time being we stifled our curiosity about any other scientific problems that may have arisen during the work of the interpretation. Having followed one path to its end, we may now retrace our steps and choose another starting-point for our rambles through the problems of dream-life: for the time being, we may leave the topic of wish-fulfilment on one side, though we are still far from having exhausted it.

Now that the application of our procedure for interpreting dreams enables us to disclose a *latent* content in them which is of far greater significance than their *manifest* one, the pressing task at once arises of re-examining one by one the various problems raised by dreams, to see whether we may not now be in a position to find satisfactory solutions for the conundrums and contradictions which seemed intractable so long as we were only acquainted with the manifest content.

In the first chapter I have given a detailed account of the views of the authorities on the relation of dreams with waking life and on the origin of the material of dreams. No doubt, too, my readers will recall the three characteristics of memory in dreams, which have been so often remarked on but which have never been explained:

(1) Dreams show a clear preference for the impressions of the immediately preceding days. Cf. Robert, Strümpell, Hildebrandt and Hallam and Weed.

(2) They make their selection upon different principles from our waking memory, since they do not recall what is essential and important but what is subsidiary and unnoticed.

(3) They have at their disposal the earliest impressions of our childhood and even bring up details from that period of our life which, once again, strike us as trivial and which in our waking state we believe to have been long since forgotten.¹

All these peculiarities shown by dreams in their choice of material have, of course, only been studied by earlier writers in connection with their *manifest* content.

¹ The view adopted by Robert that the purpose of dreams is to unburden our memory of the useless impressions of daytime is plainly no longer tenable if indifferent memory images from our childhood appear at all frequently in dreams. Otherwise we could only conclude that dreams perform their function most inadequately.

(A)

RECENT AND INDIFFERENT MATERIAL IN DREAMS

If I examine my own experience on the subject of the origin of the elements included in the content of dreams, I must begin with an assertion that in every dream it is possible to find a point of contact with the experiences of the previous day. This view is confirmed by every dream that I look into, whether my own or anyone else's. Bearing this fact in mind, I am able, on occasion, to begin a dream's interpretation by looking for the event of the previous day which set it in motion; in many instances, indeed, this is the easiest method. In the two dreams which I have analysed in detail in my last chapters (the dream of Irma's injection and the dream of my uncle with a yellow beard) the connection with the previous day is so obvious as to require no further comment. But in order to show the regularity with which such a connection can be traced, I will go through the records of my own dreams and give some instances. I shall only quote enough of the dream to indicate the source we are looking for:

(1) *I was visiting a house into which I had difficulty in gaining admittance . . . ; in the meantime I kept a lady WAITING.*

Source: I had had a conversation with a female relative the evening before in which I had told her that she would have to *wait* for a purchase she wanted to make till . . . etc.

(2) *I had written a MONOGRAPH on certain (indistinct) species of plant.*

Source: That morning I had seen a *monograph* on the genus *Cyclamen* in the window of a book-shop.

(3) *I saw two women in the street, A MOTHER AND DAUGHTER, the latter of whom was a patient of mine.*

Source: One of my patients had explained to me the previous evening the difficulties her *mother* was putting in the way of her continuing her treatment.

(4) *I took out a subscription in S. and R.'s bookshop for a periodical costing TWENTY FLORINS a year.*

Source: My wife had reminded me the day before that I still owed her *twenty florins* for the weekly household expenses.

(5) *I received a COMMUNICATION from the Social Democratic COMMITTEE, treating me as though I were a MEMBER.*

Source: I had received *communications* simultaneously from the Liberal Election *Committee* and from the Council of the Humanitarian League, of which latter body I was in fact a *member*.

(6) *A man standing on A CLIFF IN THE MIDDLE OF THE SEA, IN THE STYLE OF BÖCKLIN.*

Source: Dreyfus on the *Ile di Diable*; I had had news at the same time from my relatives in *England*, etc.

The question may be raised whether the point of contact with the dream is invariably the events of the *immediately* preceding day or whether it may go back to impressions derived from a rather more extensive period of the most recent past. It is unlikely that this question involves any matter of theoretical importance; nevertheless I am inclined to decide in favour of the exclusiveness of the claims of the day immediately preceding the dream - which I shall speak of as the 'dream-day'. Whenever it has seemed at first that the source of a dream was an impression two or three days earlier, closer enquiry has convinced me that the impression had been recalled on the previous day and thus that it was possible to show that a reproduction of the impression, occurring on the previous day, could be inserted between the day of the original event and the time of the dream; moreover it has been possible to indicate the contingency on the previous day which may have led to the recalling of the older impression.

On the other hand I do not feel convinced that there is any regular interval of biological significance between the instigating daytime impression and its recurrence in the dream. (Swoboda, 1904, has mentioned an initial period of eighteen hours in this connection.)¹

¹ [Footnote added 1911:] As I have mentioned in a postscript to my first chapter (p. 599 f.), Hermann Swoboda has made a far-reaching application to the mental field of the biological periodic intervals of 23 and 28 days discovered by Wilhelm Fliess. He has asserted in particular that these periods determine the emergence of the elements which appear in dreams. No essential modification in dream-interpretation would be involved if this fact were to be established; it would merely provide a fresh source of origin of dream-material. I have, however, recently made some investigations upon my own dreams, to test now far the 'theory of periodicity' is applicable to them. For this purpose I chose some specially outstanding dream-elements the time of whose appearance in real life could be determined with certainty.

The Interpretation Of Dreams

(Fragment) . . . *Somewhere in Italy. Three daughters were showing me some small curios, as though we were in an antique shop, and were sitting on my lap. I commented on one of the objects: 'Why, you got that from me', and saw plainly before me a small profile relief with the clear-cut features of Savonarola.*

When had I last seen a portrait of Savonarola? My travel-diary proved that I had been in Florence on September 4th and 5th. While I was there I thought I would show my travelling companion the medallion bearing the fanatical monk's features, let into the pavement of the Piazza della Signoria, which marks the place where he was burned. I pointed it out to him, I believe, on the morning of the 3rd. Between this impression and its reappearance in the dream $27 + 1$ days elapsed - Fliess's 'female period'. Unluckily for the conclusiveness of this example, however, I must add that on the actual 'dream-day' I had a visit (for the first time since my return) from a capable but gloomy-looking medical colleague of mine whom I had many years before nick-named 'Rabbi Savonarola'. He introduced a patient to me who was suffering from the effects of an accident to the Pontebba express, in which I myself had travelled a week earlier, and my thoughts were thus led back to my recent visit to Italy. The appearance in the content of the dream of the outstanding element 'Savonarola' is thus accounted for by my colleague's visit on the dream-day; and the interval of 28 days is deprived of its significance.

II. DREAM OF OCTOBER 10TH-11TH, 1910

I was once more working at chemistry in the University laboratory. Hofrat L. invited me to come somewhere and walked in front of me in the corridor, holding a lamp or some other instrument before him in his uplifted hand and with his head stretched forward in a peculiar attitude, with a clear-sighted (? far-sighted) look about him. Then we crossed an open space. . . . (The remainder was forgotten.)

The most outstanding point in the content of this dream was the way in which Hofrat L. held the lamp (or magnifying glass) before him, with his eyes peering into the distance. It was many years since I had last seen him; but I knew at once that he was only a substitute figure in the place of someone else, someone greater than he - Archimedes, whose statue stands near the Fountain of Arethusa at Syracuse in that very attitude, holding up his burning-glass and peering out towards the besieging army of the Romans. When did I see that statue for the first (and last) time? According to my diary it was on the evening of September 17th; and between then and the time of the dream $13 + 10 = 23$ days had elapsed - Fliess's 'male period'.

Unfortunately, when we go into the interpretation of this dream in greater detail, we once again find that the coincidence loses some of its conclusiveness. The exciting cause of the dream was the news I received on the dream-day that the clinic, in whose lecture room I was able by courtesy to deliver my lectures, was shortly to be removed to another locality. I took it for granted that its new situation would be very out of the way and told myself that in that case I might just as well not have a lecture room at my disposal at all. From that point my thoughts must have gone back to the beginning of my career as University Lecturer when I in fact had no lecture room and when my efforts to get hold of one met with little response from the powerfully placed Hofrats and Professors. In those circumstances I had gone to L., who at that time held the office of Dean of the Faculty and who I believed was friendly disposed to me, to complain of my troubles. He promised to help me, but I heard nothing more from him. In the dream he was Archimedes, giving me a *πρου σου* [footing] and himself leading me to the new locality. Anyone who is an adept at interpretation will guess that the dream-thoughts were not exactly free from ideas of vengeance and self-importance. It seems clear, in any case, that without this exciting cause Archimedes would scarcely have found his way into my dream that night; nor am I convinced that the powerful and still recent impression made on me by the statue in Syracuse might not have produced its effect after some different interval of time.

III. DREAM OF OCTOBER 2ND-3rd, 1910

(Fragment) . . . *Something about Professor Oser, who had drawn up the menu for me himself, which had a very soothing effect. . . .* (Some more that was forgotten.)

This dream was a reaction to a digestive disturbance that day, which made me consider whether I should go to one of my colleagues to have a dietary prescribed for me. My reason for choosing Oser for that purpose, who had died in the course of the summer, went back to the death of another University teacher whom I greatly admired, which had occurred shortly before (on October 1st). When had Oser died? and when had I heard of his death? According to a paragraph in the papers he had died on August 22nd. I had been in Holland at that time and had my Vienna newspaper sent on to me regularly; so that I must have read of his death on August 24th or 25th. But here the interval no longer corresponds to either period. It amounts to $7 + 30 + 2 = 39$ days or possibly 40 days. I could not recall having spoken or thought of Oser in the meantime.

Intervals such as this one, which cannot be fitted into the theory of periodicity without further manipulation, occur far more frequently in my dreams than intervals which *can* be so fitted. The only relation which I find occurs with regularity is the relation which I have insisted upon in the text and which connects the dream with some impression of the dream-day.

Havelock Ellis, who has also given some attention to this point, declares that he was unable to find any such periodicity in his dreams in spite of looking for it. He records a dream of being in Spain and of wanting to go to a place called Daraus, Varaus or Zaraus. On waking he could not recall any such place-name, and put the dream on one side. A few months later he discovered that Zaraus was in fact the name of a station on the line between San Sebastian and Bilbao, through which his train had passed 250 days before he had the dream.

I believe, then, that the instigating agent of every dream is to be found among the experiences which one has not yet 'slept on'. Thus the relations of a dream's content to impressions of the most recent past (with the single exception of the day immediately preceding the night of the dream) differ in no respect from its relations to impressions dating from any remoter period. Dreams can select their material from any part of the dreamer's life, provided only that there is a train of thought linking the experience of the dream-day (the 'recent' impressions) with the earlier ones.

But why this preference for recent impressions? We shall form some notion on this point, if we submit one of the dreams in the series I have just quoted to a fuller analysis. For this purpose I shall choose the

DREAM OF THE BOTANICAL MONOGRAPH

I had written a monograph on a certain plant. The book lay before me and I was at the moment turning over a folded coloured plate. Bound up in each copy there was a dried specimen of the plant, as though it had been taken from a herbarium.

ANALYSIS

That morning I had seen a new book in the window of a book-shop, bearing the title *The Genus Cyclamen* - evidently a *monograph* on that plant.

Cyclamens, I reflected, were my wife's *favourite flowers* and I reproached myself for so rarely remembering to *bring* her *flowers*, which was what she liked. - The subject of '*bringing flowers*' recalled an anecdote which I had recently repeated to a circle of friends and which I had used as evidence in favour of my theory that forgetting is very often determined by an unconscious purpose and that it always enables one to deduce the secret intentions of the person who forgets. A young woman was accustomed to receiving a bouquet of flowers from her husband on her birthday. One year this token of his affection failed to appear, and she burst into tears. Her husband came in and had no idea why she was crying till she told him that to-day was her birthday. He clasped his hand to his head and exclaimed: 'I'm so sorry, but I'd quite forgotten. I'll go out at once and fetch your *flowers*.' But she was not to be consoled; for she recognized that her husband's forgetfulness was a proof that she no longer had the same place in his thoughts as she had formerly. - This lady, Frau L., had met my wife two days before I had the dream, had told her that she was feeling quite well and enquired after me. Some years ago she had come to me for treatment.

I now made a fresh start. Once, I recalled, I really *had* written something in the nature of a *monograph on a plant*, namely a dissertation on the *coca-plant*, which had drawn Karl Koller's attention to the anaesthetic properties of cocaine. I had myself indicated this application of the alkaloid in my published paper, but I had not been thorough enough to pursue the matter further. This reminded me that on the morning of the day after the dream - I had not found time to interpret it till the evening - I had thought about cocaine in a kind of day-dream. If ever I got glaucoma, I had thought, I should travel to Berlin and get myself operated on, incognito, in my friend's house, by a surgeon recommended by him. The operating surgeon, who would have no idea of my identity, would boast once again of how easily such operations could be performed since the introduction of cocaine; and I should not give the slightest hint that I myself had had a share in the discovery. This phantasy had led on to reflections of how awkward it is, when all is said and done, for a physician to ask for medical treatment for himself from his professional colleagues. The Berlin eye-surgeon would not know me, and I should be able to pay his fees like anyone else. It was not until I had recalled this day-dream that I realized that the recollection of a specific event lay behind it. Shortly after Koller's discovery, my father had in fact been attacked by glaucoma; my friend Dr. Königstein, the ophthalmic surgeon, had operated on him; while Dr. Koller had been in charge of the cocaine anaesthesia and had commented on the fact that this case had brought together all of the three men who had had a share in the introduction of cocaine.

My thoughts then went on to the occasion when I had last been reminded of this business of the cocaine. It had been a few days earlier, when I had been looking at a copy of a *Festschrift* in which grateful pupils had celebrated the jubilee of their teacher and laboratory director. Among the laboratory's claims to distinction which were enumerated in this book I had seen a mention of the fact that Koller had made his discovery there of the anaesthetic properties of cocaine. I then suddenly perceived that my dream was connected with an event of the previous evening. I had walked home precisely with Dr. Königstein and had got into conversation with him about a matter which never fails to excite my feelings whenever it is raised. While I was talking to him in the entrance-hall, Professor Gärtner and his wife had joined us; and I could not help congratulating them both on their *blooming* looks. But Professor Gärtner was one of the authors of the *Festschrift* I have just mentioned, and may well have reminded me of it. Moreover, the Frau L., whose disappointment on her birthday I described earlier, was mentioned - though only, it is true, in another connection - in my conversation with Dr. Königstein.

I will make an attempt at interpreting the other determinants of the content of the dream as well. There was a *dried specimen of the plant* included in the monograph, as though it had been a *herbarium*. This led me to a memory from my secondary school. Our headmaster once called together the boys from the higher forms and handed over the school's herbarium to them to be looked through and cleaned. Some small *worms* - book worms - had found their way into it. He does not seem to have had much confidence in my helpfulness, for he handed me only a few sheets. These, as I could still recall, included some Crucifers. I never had a specially intimate contact with botany. In my preliminary examination in botany I was also given a Crucifer to identify - and failed to do so. My prospects would not have been too bright, if I had not been helped out by my theoretical knowledge. I went on from the Cruciferae to the Compositae. It occurred to me that artichokes were Compositae, and indeed I might fairly have called them my *favourite flowers*. Being more generous than I am, my wife often brought me back these favourite flowers of mine from the market.

I saw the monograph which I had written *lying before me*. This again led me back to something. I had had a letter from my friend in Berlin the day before in which he had shown his power of visualization: 'I am very much occupied with your dream-book. *I see it lying finished before me and I see myself turning over its pages*. How much I envied him his gift as a seer! If only *I* could have seen it lying finished before me!

The folded coloured plate. While I was a medical student I was the constant victim of an impulse only to learn things out of *monographs*. In spite of my limited means, I succeeded in getting hold of a number of volumes of the proceedings of medical societies and was enthralled by their *coloured plates*. I was proud of my hankering for thoroughness. When I myself had begun to publish papers, I had been obliged to make my own drawings to illustrate them and I remembered that one of them had been so wretched that a friendly colleague had jeered at me over it. There followed, I could not quite make out how, a recollection from very early youth. It had once amused my father to hand over a book with *coloured plates* (an account of a journey through Persia) for me and my eldest sister to destroy. Not easy to justify from the educational point of view! I had been five years old at the time and my sister not yet three; and the picture of the two of us blissfully pulling the book to pieces (leaf by leaf, like an *artichoke*, I found myself saying) was almost the only plastic memory that I retained from that period of my life. Then, when I became a student, I had developed a passion for collecting and owning books, which was analogous to my liking for learning out of monographs: a *favourite hobby*. (The idea of 'favourite' had already appeared in connection with cyclamens and artichokes.) I had become a *book-worm*. I had always, from the time I first began to think about myself, referred this first passion of mine back to the childhood memory I have mentioned. Or rather, I had recognized that the childhood scene was a 'screen memory' for my later bibliophile propensities.¹ And I had early discovered, of course, that passions often lead to sorrow. When I was seventeen I had run up a largish account at the bookseller's and had nothing to meet it with; and my father had scarcely taken it as an excuse that my inclinations might have chosen a worse outlet. The recollection of this experience from the later years of my youth at once brought back to my mind the conversation with my friend Dr. Königstein. For in the course of it we had discussed the same question of my being blamed for being too much absorbed in my *favourite hobbies*.

¹ Cf. my paper on screen memories.

For reasons with which we are not concerned, I shall not pursue the interpretation of this dream any further, but will merely indicate the direction in which it lay. In the course of the work of analysis I was reminded of my conversation with Dr. Königstein, and I was brought to it from more than one direction. When I take into account the topics touched upon in that conversation, the meaning of the dream becomes intelligible to me. All the trains of thought starting from the dream - the thoughts about my wife's and my own favourite flowers, about cocaine, about the awkwardness of medical treatment among colleagues, about my preference for studying monographs and about my neglect of certain branches of science such as botany - all of these trains of thought, when they were further pursued, led ultimately to one or other of the many ramifications of my conversation with Dr. Königstein. Once again the dream, like the one we first analysed - the dream of Irma's injection - turns out to have been in the nature of a self-justification, a plea on behalf of my own rights. Indeed, it carried the subject that was raised in the earlier dream a stage further and discussed it with reference to fresh material that had arisen in the interval between the two dreams. Even the apparently indifferent form in which the dream was couched turns out to have had significance. What it meant was: 'After all, I'm the man who wrote the valuable and memorable paper (on cocaine)', just as in the earlier dream I had said on my behalf: 'I'm a conscientious and hard-working student.' In both cases what I was insisting was: 'I may allow myself to do this.' There is, however, no need for me to carry the interpretation of the dream any further, since my only purpose in reporting it was to illustrate by an example the relation between the content of a dream and the experience of the previous day which provoked it. So long as I was aware only of the dream's *manifest* content, it appeared to be related only to a *single* event of the dream-day. But when the analysis was carried out, a *second* source of the dream emerged in another experience of the same day. The first of these two impressions with which the dream was connected was an indifferent one, a subsidiary circumstance: I had seen a book in a shop-window whose title attracted my attention for a moment but whose subject-matter could scarcely be of interest to me. The second experience had a high degree of psychical importance: I had had a good hour's lively conversation with my friend the eye-surgeon; in the course of it I had given him some information which was bound to affect both of us closely, and I had had memories stirred up in me which had drawn my attention to a great variety of internal stresses in my own mind. Moreover, the conversation had been interrupted before its conclusion because we had been joined by acquaintances.

We must now ask what was the relation of the two impressions of the dream-day to each other and to the dream of the subsequent night. In the manifest content of the dream only the *indifferent* impression was alluded to, which seems to confirm the notion that dreams have a preference for taking up unimportant details of waking life. All the strands of the interpretation, on the other hand, led to the *important* impression, to the one which had justifiably stirred my feelings. If the sense of the dream is judged, as it can only rightly be, by its latent content as revealed by the analysis, a new and significant fact is unexpectedly brought to light. The conundrum of why dreams are concerned only with worthless fragments of waking life seems to have lost all its meaning; nor can it any longer be maintained that waking life is not pursued further in dreams and that dreams are thus psychical activity wasted upon foolish material. The contrary is true: our dream-thoughts are dominated by the same material that has occupied us during the day and we only bother to dream of things which have given us cause for reflection in the daytime.

Why is it, then, that, though the occasion of my dreaming was a daytime impression by which I had been justifiably stirred, I nevertheless actually dreamt of something indifferent? The most obvious explanation, no doubt, is that we are once more faced by one of the phenomena of dream-distortion, which in my last chapter I traced to a psychical force acting as a censorship. My recollection of the monograph on the genus *Cyclamen* would thus serve the purpose of being an *allusion* to the conversation with my friend, just as the 'smoked salmon' in the dream of the abandoned supper-party served as an *allusion* to the dreamer's thought of her woman friend. The only question is as to the intermediate links which enabled the impression of the monograph to serve as an allusion to the conversation with the eye-surgeon, since at first sight there is no obvious connection between them. In the example of the abandoned supper-party the connection was given at once: 'smoked salmon', being the friend's favourite dish, was an immediate constituent of the group of ideas which were likely to be aroused in the dreamer's mind by the personality of her friend. In this later example there were two detached impressions which at a first glance only had in common the fact of their having occurred on the same day: I had caught sight of the monograph in the morning and had had the conversation the same evening. The analysis enabled us to solve the problem as follows: connections of this kind, when they are not present in the first instance, are woven retrospectively between the ideational content of one impression and that of the other. I have already drawn attention to the intermediate links in the present case by the words I have italicized in my record of the analysis. If there had been no influences from another quarter, the idea of the monograph on the *Cyclamen* would only, I imagine, have led to the idea of its being my wife's favourite flower, and possibly also to Frau L.'s absent bouquet. I scarcely think that these background thoughts would have sufficed to evoke a dream. As we are told in *Hamlet*:

There needs no ghost, my lord, come from the grave
To tell us this.

But, lo and behold, I was reminded in the analysis that the man who interrupted our conversation was called *Gärtner* and that I had thought his wife looked *blooming*. And even as I write these words I recall that one of my patients, who bore the charming name of *Flora*, was for a time the pivot of our discussion. These must have been the intermediate links, arising from the botanical group of ideas, which formed the bridge between the two experiences of that day, the indifferent and the stirring one. A further set of connections was then established - those surrounding the idea of cocaine, which had every right to serve as a link between the figure of Dr. Königstein and a botanical monograph which I had written; and these connections strengthened the fusion between the two groups of ideas so that it became possible for a portion of the one experience to serve as an allusion to the other one.

I am prepared to find this explanation attacked on the ground of its being arbitrary or artificial. What, it may be asked, would have happened if Professor Gärtner and his wife with her blooming looks had not come up to us or if the patient we were talking about had been called Anna instead of Flora? The answer is simple. If these chains of thought had been absent others would no doubt have been selected. It is easy enough to construct such chains, as is shown by the puns and riddles that people make every day for their entertainment. The realm of jokes knows no boundaries. Or, to go a stage further, if there had been no possibility of forging enough intermediate links between the two impressions, the dream would simply have been different. Another indifferent impression of the same day - for crowds of such impressions enter our minds and are then forgotten - would have taken the place of the 'monograph' in the dream, would have linked up with the subject of the conversation and would have represented it in the content of the dream. Since it was in fact the monograph and not any other idea that was chosen to serve this function, we must suppose that it was the best adapted for the connection. There is no need for us to emulate Lessing's Hänschen Schlauf and feel astonished that 'only the rich people own the most money'.

A psychological process by which, according to our account, indifferent experiences take the place of psychically significant ones, cannot fail to arouse suspicion and bewilderment. It will be our task in a later chapter to make the peculiarities of this apparently irrational operation more intelligible. At this point we are only concerned with the *effects* of a process whose reality I have been driven to assume by innumerable and regularly recurrent observations made in analysing dreams. What takes place would seem to be something in the nature of a 'displacement' - of psychical emphasis, shall we say? - by means of intermediate links; in this way, ideas which originally had only a *weak* charge of intensity take over the charge from ideas which were originally *intensely* cathected and at last attain enough strength to enable them to force an entry into consciousness. Displacements of this kind are no surprise to us where it is a question of dealing with quantities of *affect* or with motor activities in general. When a lonely old maid transfers her affection to animals, or a bachelor becomes an enthusiastic collector, when a soldier defends a scrap of coloured cloth - a flag - with his life's blood, when a few seconds' extra pressure in a hand-shake means bliss to a lover, or when, in *Othello*, a lost handkerchief precipitates an outburst of rage - all of these are instances of psychical displacements to which we raise no objection. But when we hear that a decision as to what shall reach our consciousness and what shall be kept out of it - what we shall *think*, in short - has been arrived at in the same manner and on the same principles, we have an impression of a pathological event and, if such things happen in waking life, we describe them as errors in thought. I will anticipate the conclusions to which we shall later be led, and suggest that the psychical process which we have found at work in dream-displacement, though it cannot be described as a pathological disturbance, nevertheless differs from the normal and is to be regarded as a process of a more *primary* nature.

Thus the fact that the content of dreams includes remnants of trivial experiences is to be explained as a manifestation of dream-distortion (by displacement); and it will be recalled that we came to the conclusion that dream-distortion was the product of a censorship operating in the passage-way between two psychical agencies. It is to be expected that the analysis of a dream will regularly reveal its true, psychically significant source in waking life, though the emphasis has been displaced from the recollection of that source on to that of an indifferent one. This explanation brings us into complete conflict with Robert's theory, which ceases to be of any service to us. For the fact which Robert sets out to explain is a non-existent one. His acceptance of it rests on a misunderstanding, on his failure to replace the *apparent* content of dreams by their *real* meaning. And there is another objection that can be raised to Robert's theory. If it were really the business of dreams to relieve our memory of the 'dregs' of daytime recollections by a special psychical activity, our sleep would be more tormented and harder worked than our mental life while we are awake. For the number of indifferent impressions from which our memory would need to be protected is clearly immensely large: the night would not be long enough to cope with such a mass. It is far more likely that the process of forgetting indifferent impressions goes forward without the active intervention of our psychical forces.

Nevertheless we must not be in a hurry to take leave of Robert's ideas without further consideration. We have still not explained the fact that one of the indifferent impressions of waking life, one, moreover, dating from the day preceding the dream, invariably contributes towards the dream's content. The connections between this impression and the true source of the dream in the unconscious are not always there ready-made; as we have seen, they may only be established retrospectively, in the course of the dream-work, with a view, as it were, to making the intended displacement feasible. There must therefore be some compelling force in the direction of establishing connections precisely with a recent, though indifferent, impression; and the latter must possess some attribute which makes it especially suitable for this purpose. For if that were not so, it would be just as easy for the dream-thoughts to displace their emphasis on to an unimportant component in their *own* circle of ideas.

The following observations may help us towards clearing up this point. If in the course of a single day we have two or more experiences suitable for provoking a dream, the dream will make a combined reference to them as a single whole; *it is under a necessity to combine them into a unity*. Here is an instance. One afternoon during the summer I entered a railway compartment in which I found two acquaintances who were strangers to each other. One of them was an eminent medical colleague and the other was a member of a distinguished family with which I had professional relations. I introduced the two gentlemen to each other, but all through the long journey they conducted their conversation with me as a go-between, so that I presently found myself discussing various topics alternately, first with the one and then with the other. I asked my doctor friend to use his influence on behalf of a common acquaintance of ours who was just starting a medical practice. The doctor replied that he was convinced of the young man's capacity, but that his homely appearance would make it hard for him to make his way in families of the better class; to which I replied that that was the very reason why he needed influential assistance. Turning to my other fellow-traveller, I enquired after the health of his aunt - the mother of one of my patients - who was lying seriously ill at the time. During the night following the journey I had a dream that the young friend on whose behalf I had pleaded was sitting in a fashionable drawing-room in a select company composed of all the distinguished and wealthy people of my acquaintance and, with the easy bearing of a man of the world, was delivering a funeral oration on the old lady (who was already dead so far as my dream was concerned), the aunt of my second fellow-traveller. (I must confess that I had not been on good terms with that lady.) Thus my dream had, once again, worked out connections between the two sets of impressions of the previous day and had combined them into a single situation.

Many experiences such as this lead me to assert that the dream-work is under some kind of necessity to combine all the sources which have acted as stimuli for the dream into a single unity in the dream itself.¹

¹ The tendency of the dream-work to fuse into a single action all events of interest which occur simultaneously has already been remarked on by several writers; e.g. Delage (1891, 41) and Delboeuf (1885, 237), who speaks of '*rapprochement forcé*' ['enforced convergence'].

I will now proceed to the question of whether the instigating source of a dream, revealed by analysis, must invariably be a recent (and significant) event or whether an internal experience, that is, the *recollection* of a psychically important event - a train of thought - can assume the role of a dream-instigator. The answer, based upon a large number of analyses, is most definitely in favour of the latter alternative. A dream can be instigated by an internal process which has, as it were, become a recent event, owing to thought-activity during the previous day. This seems to be the appropriate moment for tabulating the different conditions to which we find that the sources of dreams are subject. The source of a dream may be either -

- (a) a recent and psychically significant experience which is represented in the dream directly,¹ or
- (b) several recent and significant experiences which are combined into a single unity by the dream,² or
- (c) one or more recent and significant experiences which are represented in the content of the dream by a mention of a contemporary but indifferent experience,³ or
- (d) an internal significant experience (e.g. a memory or a train of thought), which is in that case *invariably* represented in the dream by a mention of a recent but indifferent impression.⁴

It will be seen that in interpreting dreams we find one condition always fulfilled: one component of the content of the dream is a repetition of a recent impression of the previous day. This impression that is to be represented in the dream may either itself belong to the circle of ideas surrounding the actual instigator of the dream - whether as an essential or as a trivial portion of it - or it may be derived from the field of an indifferent impression which has been brought into connection with the ideas surrounding the dream-instigator by more or less numerous links. The apparent multiplicity of governing conditions is in fact merely dependent upon the two alternatives of whether a displacement has or has not taken place; and it is worth pointing out that we are enabled by thesatives to explain the range of contrast between different dreams just as easily as the medical theory is enabled to do by its hypothesis of brain-cells ranging from partial to total wakefulness. (See above, p. 583 ff.)

¹ As in the dream of Irma's injection and in the dream of my uncle with the yellow beard.

² As in the young doctor's funeral oration.

³ As in the dream of the botanical monograph.

⁴ Most of my patient's dreams during analysis are of this kind.

It will further be observed, if we consider these four possible cases, that a psychical element which is significant but not recent (e.g. a train of thought or a memory) can be replaced, for the purpose of forming a dream, by an element which is recent but indifferent, provided only that two conditions are fulfilled: (1) the content of the dream must be connected with a recent experience, and (2) the instigator of the dream must remain a psychically significant process. Only in one case - case (a) - are both of these conditions fulfilled by one and the same impression. It is to be noticed, moreover, that indifferent impressions which are capable of being used for constructing a dream so long as they are recent lose that capacity as soon as they are a day (or at the most a few days) older. From this we must conclude that the freshness of an impression gives it some kind of psychical value for purposes of dream-construction equivalent in some way to the value of emotionally coloured memories or trains of thought. The basis of the value which thus attaches to recent impressions in connection with the construction of dreams will only become evident in the course of our subsequent psychological discussions.¹

In this connection it will be noticed, incidentally, that modifications in our mnemonic and ideational material may take place during the night unobserved by our consciousness. We are often advised that before coming to a final decision on some subject we should 'sleep on it', and this advice is evidently justified. But here we have passed from the psychology of dreams to that of sleep, and this is not the last occasion on which we shall be tempted to do so.²

¹ See the passage on 'transference' in Chapter VII.

² [*Footnote added 1919:*] An important contribution to the part played by recent material in the construction of dreams has been made by Pözl (1917) in a paper which carries a wealth of implications. In a series of experiments Pözl required the subjects to make a drawing of what they had consciously noted of a picture exposed to their view in a tachistoscope. He then turned his attention to the dreams dreamt by the subjects during the following night and required them once more to make drawings of appropriate portions of these dreams. It was shown unmistakably that those details of the exposed picture which had not been noted by the subject provided material for the construction of the dream, whereas those details which had been consciously perceived and recorded in the drawing made after the exposure did not recur in the manifest content of the dream. The material that was taken over by the dream-work was modified by it for the purposes of dream-construction in its familiar 'arbitrary' (or, more properly, 'autocratic') manner. The questions raised by Pözl's experiment go far beyond the sphere of dream-interpretation as dealt with in the present volume. In passing, it is worth remarking on the contrast between this new method of studying the formation of dreams experimentally and the earlier, crude technique for introducing into the dream stimuli which interrupted the subject's sleep.

An objection, however, may be raised which threatens to upset these last conclusions. If indifferent impressions can only find their way into a dream provided they are recent, how does it happen that the content of dreams also includes elements from an earlier period of life which at the time when they were recent possessed, to use Strümpell's words, no psychical value, and should therefore have been long since forgotten - elements, that is to say, which are neither fresh nor psychically significant?

This objection can be completely dealt with by a reference to the findings of the psycho-analysis of neurotics. The explanation is that the displacement which replaces psychically important by indifferent material (alike in dreaming and in thinking) has in these cases already taken place at the early period of life in question and since then become fixed in the memory. These particular elements which were originally indifferent are indifferent no longer, since taking over (by means of displacement) the value of psychically significant material. Nothing that has *really* remained indifferent can be reproduced in a dream.

The reader will rightly conclude from the foregoing arguments that I am asserting that there are no indifferent dream-instigators - and consequently no 'innocent' dreams. Those are, in the strictest and most absolute sense, my opinions - if I leave on one side the dreams of children and perhaps brief reactions in dreams to sensations felt during the night. Apart from this, what we dream is either manifestly recognizable as psychically significant, or it is distorted and cannot be judged till the dream has been interpreted, after which it will once more be found to be significant. Dreams are never concerned with trivialities; we do not allow our sleep to be disturbed by trifles.¹ The apparently innocent dreams turn out to be quite the reverse when we take the trouble to analyse them. They are, if I may say so, wolves in sheep's clothing. Since this is another point upon which I may expect to be contradicted, and since I am glad of an opportunity of showing dream-distortion at work, I will select a number of 'innocent' dreams from my records and submit them to analysis.

¹ [Footnote added 1914:] Havelock Ellis, a friendly critic of this book, writes (1911, 166): 'This is the point at which many of us are no longer able to follow Freud.' Havelock Ellis has not, however, carried out any analyses of dreams and refuses to believe how impossible it is to base one's judgement on their manifest content.

I

An intelligent and cultivated young woman, reserved and undemonstrative in her behaviour, reported as follows: *I dreamt that I arrived too late at the market and could get nothing either from the butcher or from the woman who sells vegetables.* An innocent dream, no doubt; but dreams are not as simple as that, so I asked to be told it in greater detail. She thereupon gave me the following account. *She dreamt she was going to the market with her cook, who was carrying the basket. After she had asked for something, the butcher said to her: 'That's not obtainable any longer', and offered her something else, adding 'This is good too.' She rejected it and went on to the woman who sells vegetables, who tried to get her to buy a peculiar vegetable that was tied up in bundles but was of a black colour. She said: 'I don't recognize that; I won't take it.'*

The dream's connection with the previous day was quite straightforward. She had actually gone to the market too late and had got nothing. The situation seemed to shape itself into the phrase '*Die Flieschbank war schon gescholossen*'. I pulled myself up: was not that, or rather its opposite, a vulgar description of a certain sort of slovenliness in a man's dress? However, the dreamer herself did not use the phrase; she may perhaps have avoided using it. Let us endeavour, then, to arrive at an interpretation of the details of the dream.

When anything in a dream has the character of direct speech, that is to say, when it is said or heard and not merely thought (and it is easy as a rule to make the distinction with certainty), then it is derived from something actually spoken in waking life - though, to be sure, this something is merely treated as raw material and may be cut up and slightly altered and, more especially, divorced from its context.¹ In carrying out an interpretation, one method is to start from spoken phrases of this kind. What, then, was the origin of the butcher's remark '*That's not obtainable any longer*'? The answer was that it came from me myself. A few days earlier I had explained to the patient that the earliest experiences of childhood were '*not obtainable any longer* as such', but were replaced in analysis by 'transferences' and dreams. So *I* was the butcher and she was rejecting these transferences into the present of old habits of thinking and feeling. - What, again, was the origin of her own remark in the dream '*I don't recognize that; I won't take it*'? For the purposes of the analysis this had to be divided up. '*I don't recognize that*' was something she had said the day before to her cook, with whom she had had a dispute; but at the time she had gone on: '*Behave yourself properly!*' At this point there had clearly been a displacement. Of the two phrases that she had used in the dispute with her cook, she had chosen the insignificant one for inclusion in the dream. But it was only the suppressed one, '*Behave yourself properly!*' that fitted in with the rest of the content of the dream: those would have been the appropriate words to use if someone had ventured to make improper suggestions and had forgotten 'to close his meat-shop'. The allusions underlying the incident with the vegetable-seller were a further confirmation that our interpretation was on the right track. A vegetable that is sold tied up in bundles (lengthways, as the patient added afterwards) and is also black, could only be a dream-combination of asparagus and black (Spanish) radishes. No knowledgeable person of either sex will ask for an interpretation of asparagus. But the other vegetable - '*Schwarzer Retting*' - can be taken as an exclamation - '*Schwarzer rett' dich!*' -, and accordingly it too seems to hint at the same sexual topic which we suspected at the very beginning, when we felt inclined to introduce the phrase about the meat-shop being closed into the original account of the dream. We need not enquire now into the full meaning of the dream. So much is quite clear: it *had* a meaning and that meaning was far from innocent.²

¹ See my discussion of speeches in dreams in my chapter on the dream-work. Only one writer on the subject seems to have recognized the source of spoken phrases occurring in dreams, namely Delboeuf (1885, 226), who compares them to *clichés*.

² If anyone is curious to know, I may add that the dream concealed a phantasy of my behaving in an improper and sexually provocative manner, and of the patient putting up a defence against my conduct. If this interpretation seems incredible, I need only point to the numerous instances in which doctors have charges of the same kind brought against them by hysterical women. But in such cases the phantasy emerges into consciousness undisguised and in the form of a delusion, instead of being distorted and appearing only as a dream. - [Added 1909:] This dream occurred at the beginning of the patient's psycho-analytic treatment. It was not until later that I learnt that she had been repeating in it the initial trauma from which her neurosis had arisen. I have since then come across the same behaviour in other patients; having been exposed to a sexual assault in their childhood, they seek, as it were, to bring about a repetition of it in their dreams.

II

Here is another innocent dream, dreamt by the same patient, and in a sense a counterpart to the last one. *Her husband asked her: 'Don't you think we ought to have the piano tuned?' And she replied: 'It's not worth while; the hammers need reconditioning in any case.'*

Once again this was a repetition of a real event of the previous day. Her husband had asked this question and she had made some such reply. But what was the explanation of her dreaming it? She told me that the piano was a *disgusting* old *box*, that it made an *ugly noise*, that it had been in her husband's possession before their marriage,¹ and so on. But the key to the solution was only given by her words: *'It's not worth while.'* These were derived from a visit she had paid the day before to a woman friend. She had been invited to take off her jacket, but had refused with the words: *'Thank you, but its not worth while; I can only stop a minute.'* As she was telling me this, I recollected that during the previous day's analysis she had suddenly caught hold of her jacket, one of the buttons having come undone. Thus it was as though she were saying: *'Please don't look; its not worth while.'* In the same way the 'box' [*Kasten*] was a substitute for a 'chest' [*Bruskasten*]; and the interpretation of the dream led us back at once to the time of her physical development at puberty, when she had begun to be dissatisfied by her figure. We can hardly doubt that it led back to still earlier times, if we take the word *'disgusting'* into account and the *'ugly noise'*, and if we remember how often - both in *double entendres* and in dreams - the lesser hemispheres of a woman's body are used, whether as contrasts or as substitutes, for the larger ones.

¹ This last was a substitute for the opposite idea, as the course of the analysis will make clear.

III

I will interrupt this series for a moment and insert a short innocent dream produced by a young man. He dreamt that *he was putting on his winter overcoat once more, which was a dreadful thing*. The ostensible reason for this dream was a sudden return of cold weather. If we look more closely, however, we shall notice that the two short pieces that make up the dream are not in complete harmony. For what could there be 'dreadful' about putting on a heavy or thick overcoat in cold weather? Moreover, the innocence of the dream was decidedly upset by the first association that occurred to the dreamer in the analysis. He recalled that a lady confided to him the day before that her youngest child owed its existence to a torn condom. On that basis he was able to reconstruct his thoughts. A thin condom was dangerous, but a thick one was bad. The condom was suitably represented as an overcoat, since one slips into both of them. But an occurrence such as the lady described to him would certainly be 'dreadful' for an unmarried man.

And now let us return to our innocent lady dreamer.

IV

She was putting a candle into a candlestick; but the candle broke so that it wouldn't stand up properly. The girls at her school said she was clumsy; but the mistress said it was not her fault.

Yet again the occasion for the dream was a real event. The day before she had actually put a candle into a candlestick, though it did not break. Some transparent symbolism was being used in this dream. A candle is an object which can excite the female genitals; and, if it is broken, so that it cannot stand up properly, it means that the man is impotent. (*'It was not her fault.'*) But could a carefully brought-up young woman, who had been screened from the impact of anything ugly, have known that a candle might be put to such a use? As it happened, she was able to indicate how it was that she obtained this piece of knowledge. Once when they were in a rowing boat on the Rhine, another boat had passed them with some students in it. They were in high spirits and were singing, or rather shouting, a song:

Wenn die Königin von Schweden,
Bei geschlossenen Fensterläden
Mit Apollokerzen . . .¹

She either failed to hear or did not understand the last word and had to get her husband to give her the necessary explanation. The verse was replaced in the content of the dream by an innocent recollection of some job she had done clumsily when she was at school, and the replacement was made possible owing to the common element of *closed shutters*. The connection between the topics of masturbation and impotence is obvious enough. The 'Apollo' in the latent content of this dream linked it with an earlier one in which the virgin Pallas figured. Altogether far from innocent.

¹ ['When the Queen of Sweden, behind closed shutters, . . . with Apollo candles.' The missing word is '*onaniert*' ('masturbates').]

V

In order that we may not be tempted to draw conclusions too easily from dreams as to the dreamer's actual life, I will add one more dream of the same patient's, which once more has an innocent appearance. '*I dreamt,*' she said, '*of what I really did yesterday: I filled a small trunk so full of books that I really had difficulty in shutting it and I dreamt what really happened.*' In this instance the narrator herself laid the chief emphasis on the agreement between the dream and reality. All such judgements on a dream and comments upon it, though they have made themselves a place in waking thought, invariably form in fact part of the latent content of the dream, as we shall find confirmed by other examples later on. What we were being told, then, was that what the dream described had really happened the day before. It would take up too much space to explain how it was that the idea occurred to me of making use of the English language in the interpretation. It is enough to say that once again what was in question was a little 'box' (cf. the dream of the dead child in the 'case', p. 649 f.) which was so full that nothing more could get into it. Anyhow, nothing bad this time.

In all of these 'innocent' dreams the motive for the censorship is obviously the sexual factor. This, however, is a subject of prime importance which I must leave on one side.

(B)

INFANTILE MATERIAL AS A SOURCE OF DREAMS

Like every other writer on the subject, with the exception of Robert, I have pointed out as a third peculiarity of the content of dreams that it may include impressions which date back to earliest childhood, and which seem not to be accessible to waking memory. It is naturally hard to determine how rarely or how frequently this occurs, since the origin of the dream elements in question is not recognized after waking. Proof that what we are dealing with are impressions from childhood must therefore be established by external evidence and there is seldom an opportunity for doing this. A particularly convincing example is that given by Maury of the man who determined one day to revisit his old home after an absence of more than twenty years. During the night before his departure he dreamt that he was in a totally unknown place and there met an unknown man in the street and had a conversation with him. When he reached his home, he found that the unknown place was a real one in the immediate neighbourhood of his native town, and the unknown man in the dream turned out to be a friend of his dead father's who was still living there. This was conclusive evidence that he had seen both the man and the place in his childhood. This dream is also to be interpreted as a dream of impatience like that of the girl with the concert-ticket in her pocket (p. 647 f.), that of the child whose father had promised to take her on an excursion to the Hameau (cf. p. 628 f.), and similar ones. The motives which led the dreamers to reproduce one particular impression from their childhood rather than any other cannot, of course, be discovered without an analysis.

Someone who attended a course of lectures of mine and boasted that his dreams very seldom underwent distortion reported to me that not long before he had dreamt of seeing *his former tutor in bed with the nurse* who had been with his family till his eleventh year. In the dream he had identified the locality where the scene occurred. His interest had been aroused and he had reported the dream to his elder brother, who had laughingly confirmed the truth of what he had dreamt. His brother remembered it very well, as he had been six years old at the time. The lovers had been in the habit of making the elder boy drunk with beer, whenever circumstances were favourable for intercourse during the night. The younger boy - the dreamer - who was then three years old and slept in the room with the nurse, was not regarded as an impediment.

There is another way in which it can be established with certainty without the assistance of interpretation that a dream contains elements from childhood. This is where the dream is of what has been called the 'recurrent' type: that is to say, where a dream was first dreamt in childhood and then constantly reappears from time to time during adult sleep. I am able to add to the familiar examples of such dreams a few from my own records, though I have never myself experienced one. A physician in his thirties told me that from the earliest days of his childhood to the present time a yellow lion frequently appeared in his dreams; he was able to give a minute description of it. This lion out of his dreams made its appearance one day in bodily form, as a china ornament that had long disappeared. The young man then learnt from his mother that this object had been his favourite toy during his early childhood, though he himself had forgotten the fact.

If we turn now from the manifest content of dreams to the dream-thoughts which only analysis uncovers, we find to our astonishment that experiences from childhood also play a part in dreams whose content would never have led one to suppose it. I owe a particularly agreeable and instructive example of a dream of this kind to my respected colleague of the yellow lion. After reading Nansen's narrative of his polar expedition, he had a dream of being in a field of ice and of giving the gallant explorer galvanic treatment for an attack of sciatica from which he was suffering. In the course of analysing the dream, he thought of a story dating from his childhood, which alone, incidentally, made the dream intelligible. One day, when he was a child of three or four, he had heard the grown-ups talking of voyages of discovery and had asked his father whether that was a serious illness. He had evidently confused '*Reisen*' ['voyages'] with '*Reissen*' ['gripes'], and his brothers and sisters saw to it that he never forgot this embarrassing mistake.

There was a similar instance of this when, in the course of my analysis of the dream of the monograph on the genus *Cyclamen*, I stumbled upon the childhood memory of my father, when I was a boy of five, giving me a book illustrated with coloured plates to destroy. It may perhaps be doubted whether this memory really had any share in determining the form taken by the content of the dream or whether it was not rather that the process of analysis built up the connection subsequently. But the copious and intertwined associative links warrant our accepting the former alternative: cyclamen - favourite flower - favourite food - artichokes; pulling to pieces like an artichoke, leaf by leaf (a phrase constantly ringing in our ears in relation to the piecemeal dismemberment of the Chinese Empire) - herbarium - book-worms, whose favourite food is books. Moreover I can assure my readers that the ultimate meaning of the dream, which I have not disclosed, is intimately related to the subject of the childhood scene.

In the case of another group of dreams, analysis shows us that the actual wish which instigated the dream, and the fulfilment of which is represented by the dream, is derived from childhood; so that, to our surprise, *we find the child and the child's impulses still living on in the dream.*

At this point I shall once more take up the interpretation of a dream which we have already found instructive - the dream of my friend R. being my uncle. We have followed its interpretation to the point of recognizing clearly as one of its motives my wish to be appointed to a professorship; and we explained the affection I felt in the dream for my friend R. as a product of opposition and revolt against the slanders upon my two colleagues which were contained in the dream-thoughts. The dream was one of my own; I may therefore continue its analysis by saying that my feelings were not yet satisfied by the solution that had so far been reached. I knew that my waking judgement upon the colleagues who were so ill-used in the dream-thoughts would have been a very different one; and the force of my wish not to share their fate in the matter of the appointment struck me as insufficient to explain the contradiction between my waking and dreaming estimates of them. If it was indeed true that my craving to be addressed with a different title was as strong as all that, it showed a pathological ambition which I did not recognize in myself and which I believed was alien to me. I could not tell how other people who believed they knew me would judge me in this respect. It might be that I was really ambitious; but, if so, my ambition had long ago been transferred to objects quite other than the title and rank of *professor extraordinarius*.

What, then, could have been the origin of the ambitiousness which produced the dream in me? At that point I recalled an anecdote I had often heard repeated in my childhood. At the time of my birth an old peasant-woman had prophesied to my proud mother that with her first-born child she had brought a great man into the world. Prophecies of this kind must be very common: there are so many mothers filled with happy expectations and so many old peasant-women and others of the kind who make up for the loss of their power to control things in the present world by concentrating it on the future. Nor can the prophetess have lost anything by her words. Could this have been the source of my thirst for grandeur? But that reminded me of another experience, dating from my later childhood, which provided a still better explanation. My parents had been in the habit, when I was a boy of eleven or twelve, of taking me with them to the Prater. One evening, while we were sitting in a restaurant there, our attention had been attracted by a man who was moving from one table to another and, for a small consideration, improvising a verse upon any topic presented to him. I was despatched to bring the poet to our table and he showed his gratitude to the messenger. Before enquiring what the chosen topic was to be, he had dedicated a few lines to myself; and he had been inspired to declare that I should probably grow up to be a Cabinet Minister. I still remembered quite well what an impression this second prophecy had made on me. Those were the days of the 'Bürger' Ministry. Shortly before, my father had brought home portraits of these middle-class professional men - Herbst, Giskra, Unger, Berger and the rest - and we had illuminated the house in their honour. There had even been some Jews among them. So henceforth every industrious Jewish schoolboy carried a Cabinet Minister's portfolio in his satchel. The events of that period no doubt had some bearing on the fact that up to a time shortly before I entered the University it had been my intention to study Law; it was only at the last moment that I changed my mind. A ministerial career is definitely barred to a medical man. But now to return to my dream. It began to dawn on me that my dream had carried me back from the dreary present to the cheerful hopes of the days of the 'Bürger' Ministry, and that the wish that it had done its best to fulfil was one dating back to those times. In mishandling my two learned and eminent colleagues because they were Jews, and in treating the one as a simpleton and the other as a criminal, I was behaving as though I were the Minister, I had put myself in the Minister's place. Turning the tables on His Excellency with a vengeance! He had refused to appoint me *professor extraordinarius* and I had retaliated in the dream by stepping into his shoes.

In another instance it became apparent that, though the wish which instigated the dream was a present-day one, it had received a powerful reinforcement from memories that stretched far back into childhood. What I have in mind is a series of dreams which are based upon a longing to visit Rome. For a long time to come, no doubt, I shall have to continue to satisfy that longing in my dreams: for at the season of the year when it is possible for me to travel, residence in Rome must be avoided for reasons of health.¹ For instance, I dreamt once that I was looking out of a railway-carriage window at the Tiber and the Ponte Sant' Angelo. The train began to move off, and it occurred to me that I had not so much as set foot in the city. The view that I had seen in my dream was taken from a well-known engraving which I had caught sight of for a moment the day before in the sitting-room of one of my patients. Another time someone led me to the top of a hill and showed me Rome half-shrouded in mist; it was so far away that I was surprised at my view of it being so clear. There was more in the content of this dream than I feel prepared to detail; but the theme of 'the promised land seen from afar' was obvious in it. The town which I saw in this way for the first time, shrouded in mist, was - Lübeck, and the prototype of the hill was - at Gleichenberg. In a third dream I had at last got to Rome, as the dream itself informed me; but I was disappointed to find that the scenery was far from being of an urban character. *There was a narrow stream of dark water; on one side of it were black cliffs and on the other meadows with big white flowers. I noticed a Herr Zucker (whom I knew slightly) and determined to ask him the way to the city.* I was clearly making a vain attempt to see in my dream a city which I had never seen in my waking life. Breaking up the landscape in the dream into its elements, I found that the white flowers took me to Ravenna, which I have visited and which, for a time at least, superseded Rome as capital of Italy. In the marshes round Ravenna we found the loveliest water-lilies growing in black water. Because we had had such difficulty in picking them out of the water, the dream made them grow in meadows like the narcissi at our own Aussee. The dark cliff, so close to the water, reminded me vividly of the valley of the Tepl near Karlsbad. '*Karlsbad*' enabled me to explain the curious detail of my having asked Herr Zucker the way. The material out of which the dream was woven included at this point two of those facetious Jewish anecdotes which contain so much profound and often bitter worldly wisdom and which we so greatly enjoy quoting in our talk and letters. Here is the first one: the '*constitution*' story. An impecunious Jew had stowed himself away without a ticket in the fast train to *Karlsbad*. He was caught, and each time tickets were inspected he was taken out of the train and treated more and more severely. At one of the stations on his *via dolorosa* he met an acquaintance, who asked him where he was travelling to. 'To *Karlsbad*', was his reply, 'if my constitution can stand it.' My memory then passed on to another story: of a Jew who could not speak French and had been recommended when he was in Paris to ask the way to the rue Richelieu. Paris itself had for many long years been another goal of my longings; and the blissful feelings with which I first set foot on its pavement seemed to me a guarantee that others of my wishes would be fulfilled as well. 'Asking the way', moreover, was a direct allusion to Rome, since it is well known that all roads lead there. Again, the name *Zucker* was once more an allusion to *Karlsbad*; for we are in the habit of prescribing treatment there for anyone suffering from the *constitutional* complaint of diabetes. The instigation to this dream had been a proposal made by my friend in Berlin that we should meet in Prague at Easter. What we were going to discuss there would have included something with a further connection with 'sugar' and 'diabetes'.

¹ [Footnote added 1909:] I discovered long since that it only needs a little courage to fulfil wishes which till then have been regarded as unattainable; [added 1925:] and thereafter became a constant pilgrim to Rome.

A fourth dream, which occurred soon after the last one, took me to Rome once more. I saw a street-corner before me and was surprised to find so many posters in German stuck up there. I had written to my friend with prophetic foresight the day before to say that I thought Prague might not be an agreeable place for a German to walk about in. Thus the dream expressed at the same time a wish to meet him in Rome instead of in a Bohemian town, and a desire, probably dating back to my student days, that the German language might be better tolerated in Prague. Incidentally, I must have understood Czech in my earliest childhood, for I was born in a small town in Moravia which has a Slav population. A Czech nursery rhyme, which I heard in my seventeenth year, printed itself on my memory so easily that I can repeat it to this day, though I have no notion what it means. Thus there was no lack of connections with my early childhood in these dreams either.

It was on my last journey to Italy, which, among other places, took me past Lake Trasimene, that finally - after having seen the Tiber and sadly turned back when I was only fifty miles from Rome - I discovered the way in which my longing for the eternal city had been reinforced by impressions from my youth. I was in the act of making a plan to by-pass Rome next year and travel to Naples, when a sentence occurred to me which I must have read in one of our classical authors:¹ 'Which of the two, it may be debated, walked up and down his study with the greater impatience after he had formed his plan of going to Rome - Winckelmann, the Vice-Principal, or Hannibal, the Commander-in-Chief' I had actually been following in Hannibal's footsteps. Like him, I had been fated not to see Rome; and he too had moved into the Campagna when everyone had expected him in Rome. But Hannibal, whom I had come to resemble in these respects, had been the favourite hero of my later school days. Like so many boys of that age, I had sympathized in the Punic Wars not with the Romans but with the Carthaginians. And when in the higher classes I began to understand for the first time what it meant to belong to an alien race, and anti-semitic feelings among the other boys warned me that I must take up a definite position, the figure of the semitic general rose still higher in my esteem. To my youthful mind Hannibal and Rome symbolized the conflict between the tenacity of Jewry and the organization of the Catholic church. And the increasing importance of the effects of the anti-semitic movement upon our emotional life helped to fix the thoughts and feelings of those early days. Thus the wish to go to Rome had become in my dream-life a cloak and symbol for a number of other passionate wishes. Their realization was to be pursued with all the perseverance and single-mindedness of the Carthaginian, though their fulfilment seemed at the moment just as little favoured by destiny as was Hannibal's lifelong wish to enter Rome.

¹ [Footnote added 1925:] The author in question must no doubt have been Jean Paul.

At that point I was brought up against the event in my youth whose power was still being shown in all these emotions and dreams. I may have been ten or twelve years old, when my father began to take me with him on his walks and reveal to me in his talk his views upon things in the world we live in. Thus it was, on one such occasion, that he told me a story to show me how much better things were now than they had been in his days. 'When I was a young man', he said, 'I went for a walk one Saturday in the streets of your birthplace; I was well dressed, and had a new fur cap on my head. A Christian came up to me and with a single blow knocked off my cap into the mud and shouted: "Jew! get off the pavement!"' 'And what did you do?' I asked. 'I went into the roadway and picked up my cap', was his quiet reply. This struck me as unheroic conduct on the part of the big, strong man who was holding the little boy by the hand. I contrasted this situation with another which fitted my feelings better: the scene in which Hannibal's father, Hamilcar Barca,¹ made his boy swear before the household altar to take vengeance on the Romans. Ever since that time Hannibal had had a place in my phantasies.

I believe I can trace my enthusiasm for the Carthaginian general a step further back into my childhood; so that once more it would only have been a question of a transference of an already formed emotional relation on to a new object. One of the first books that I got hold of when I had learnt to read was Thiers' history of the Consulate and Empire. I can still remember sticking labels on the flat backs of my wooden soldiers with the names of Napoleon's marshals written on them. And at that time my declared favourite was already Massena (or to give the name its Jewish form, Manasseh).² (No doubt this preference was also partly to be explained by the fact that my birthday fell on the same day as his, exactly a hundred years later.) Napoleon himself lines up with Hannibal owing to their both having crossed the Alps. It may even be that the development of this martial ideal is traceable still further back into my childhood: to the times when, at the age of three, I was in a close relation, sometimes friendly but some times warlike, with a boy a year older than myself, and to the wishes which that relation must have stirred up in the weaker of us.

The deeper one carries the analysis of a dream, the more often one comes upon the track of experiences in childhood which have played a part among the sources of that dream's latent content.

¹ [Footnote added 1909:] In the first edition the name of Hasdrubal appeared instead: a puzzling mistake, which I have explained in my *Psychopathology of Everyday Life* (1901b), Chapter X (2).

² [Footnote added 1930:] Incidentally, doubts have been thrown on the Marshal's Jewish origin.

We have already seen (on p. 534) that a dream very seldom reproduces recollections in such a way that they constitute, without abbreviation or modification, the *whole* of its manifest content. Nevertheless there are some undoubted instances of this happening: and I can add a few more, relating, once more, to childhood scenes. One of my patients was presented in a dream with an almost undistorted reproduction of a sexual episode, which was at once recognizable as a true recollection. His memory of the event had, in fact, never been completely lost in waking life, though it had become greatly obscured, and its revival was a consequence of work previously done in analysis. At the age of twelve, the dreamer had gone to visit a school friend who was laid up in bed, when the latter, by what was probably an accidental movement, uncovered his body. At the sight of his friend's genitals, my patient had been overcome by some sort of compulsion and had uncovered himself too and caught hold of the other's penis. His friend looked at him with indignation and astonishment; where upon, overcome by embarrassment, he let go. This scene was repeated in a dream twenty-three years later, including all the details of his feelings at the time. It was modified, however, to this extent, that the dreamer assumed the passive instead of the active role, while the figure of his school-friend was replaced by someone belonging to his contemporary life.

It is true that as a rule the childhood scene is only represented in the dream's manifest content by an allusion, and has to be arrived at by an interpretation of the dream. Such instances when they are recorded, cannot carry much conviction, since as a rule there is no other evidence of these childhood experiences having occurred: if they date back to a very early age they are no longer recognized as memories. The general justification for inferring the occurrence of these childhood experiences from dreams is provided by a whole number of factors in psycho-analytic work, which are mutually consistent and thus seem sufficiently trustworthy. If I record some of these inferred childhood experiences torn from their context for the purposes of dream-interpretation, they may perhaps create little impression, especially as I shall not even be able to quote all the material on which the interpretations were based. Nevertheless I shall not allow this to deter me from relating them.

I

All the dreams of one of my women patients were characterized by her being 'rushed': she would be in a violent rush to get somewhere in time not to miss a train, and so on. In one dream *she was going to call on a woman friend; her mother told her to take a cab and not to walk; but she ran instead and kept on falling down.* -The material which came up in analysis led to memories of *rushing* about and romping as a child. One particular dream recalled the favourite children's game of saying a sentence '*Die Kuh rannte, bis sie fiel*' ['The cow ran till it fell'] so quickly that it sounds as though it were a single word - another *rush* in fact. All these innocent rushings-about with little girl friends were remembered because they took the place of other, less innocent ones.

II

Here is another woman patient's dream: *She was in a big room in which all sorts of machines were standing, like what she imagined an orthopaedic institute to be. She was told I had no time and that she must have her treatment at the same time as five others. She refused, however, and would not lie down in the bed - or whatever it was - that was meant for her. She stood in the corner and waited for me to say it wasn't true. Meanwhile the others were laughing at her and saying it was just her way of 'carrying on.'* - *Simultaneously, it was as though she was making a lot of small squares.*

The first part of the content of this dream related to the treatment and was a transference on to me. The second part contained an allusion to a scene in childhood. The two parts were linked together by the mention of the bed.

The *orthopaedic institute* referred back to a remark I had made in which I had compared the treatment, alike in its length and in its nature, to an *orthopaedic* one. When I started her treatment I had been obliged to tell her that for the time being *I had not much time for her*, though later I should be able to give her a whole hour daily. This had stirred up her old sensitiveness, which is a principal trait in the character of children inclined to hysteria: they are insatiable for love. My patient had been the youngest of a family of six children (hence: *at the same time as five others*) and had therefore been her father's favourite; but even so she seems to have felt that her adored father devoted too little of his time and attention to her. -Her *waiting for me to say it wasn't true* had the following origin. A young tailor's apprentice had brought her a dress and she had given him the money for it. Afterwards she had asked her husband whether if the boy lost the money she would have to pay it over again. Her husband, to *tease* her, had said that was so. (The *teasing* in the dream.) She kept on asking over and over again and *waited for him to say after all it wasn't true*. It was then possible to infer that in the latent content of the dream she had had a thought of whether she would have to pay me twice as much if I gave her twice as much time - a thought which she felt was avaricious or *filthy*. (Uncleanliness in childhood is often replaced in dreams by avariciousness for money; the link between the two is the word 'filthy'.) If the whole passage about *waiting for me to say*, etc., was intended in the dream as a circumlocution for the word 'filthy', then her '*standing in the corner*' and '*not lying down in the bed*' would fit in with it as constituents of a scene from her childhood: a scene in which she had dirtied her bed and been punished by being made to stand in the corner, with a threat that her father would not love her any more and her brothers and sisters would laugh at her, and so on. -The *small squares* related to her little niece, who had shown her the arithmetical trick of arranging the digits in nine squares (I believe this is correct) so that they add up in all directions to fifteen.

III

A man dreamt as follows: *He saw two boys struggling - barrel-maker's boys, to judge by the implements lying around. One of the boys threw the other down; the boy on the ground had earrings with blue stones. He hurried towards the offender with his stick raised, to chastise him. The latter fled for protection to a woman, who was standing by a wooden fence, as though she was his mother. She was a woman of the working classes and her back was turned to the dreamer. At last she turned around and gave him a terrible look so that he ran off in terror. The red flesh of the lower lids of her eyes could be seen standing out.*

The dream had made copious use of trivial events of the previous day. He had in fact seen two boys in the street, one of whom threw the other down. When he hurried up to stop the fight they had both taken to their heels. -*Barrel-maker's boys*. This was only explained by a subsequent dream in which he used the phrase '*knocking the bottom out of a barrel*'. -From his experience he believed that *earrings with blue stones* were mostly worn by prostitutes. A line from a well-known piece of doggerel about *two boys* then occurred to him: 'The other boy was called Marie' (i.e. was a girl). -*The woman standing*. After the scene with the two boys he had gone for a walk along the bank of the Danube and had profited by the loneliness of the spot to micturate against a *wooden fence*. Further on, a respectably dressed elderly lady had smiled at him in a very friendly manner and had wanted to give him her visiting-card. Since the woman in the dream was standing in the same position as he had been in when he was micturating, it must have been a question of a micturating woman. This tallies with her terrible *look* and the *red flesh standing out*, which could only relate to the gaping of the genitals caused by stooping. This, seen in his childhood, reappeared in later memory as '*proud flesh*' - as a wound.

The dream combined two opportunities he had had as a little boy of seeing little girls' genitals: when they were *thrown down* and when they were *micturating*. And from the other part of the context it emerged that he had a recollection of being *chastised* or threatened by his father for the sexual curiosity he had evinced on these occasions.

IV

Behind the following dream (dreamt by an elderly lady) there lay a whole quantity of childhood memories, combined, as best they might be, into a single phantasy.

She went out in a violent rush to do some commissions. In the Graben she sank down on her knees, as though she was quite broken-down. A large number of people collected round her, especially cab-drivers; but no one helped her up. She made several vain attempts, and she must at last have succeeded, for she was put into a cab which was to take her home. Someone threw a big, heavily-laden basket (like a shopping-basket) in through the window after her.

This was the same lady who always felt 'rushed' in her dreams, just as she had rushed and romped about when she was a child. The first scene in the dream was evidently derived from the sight of a horse fallen down; in the same way the word '*broken-down*' referred to horse-racing. In her youth she had ridden horses, and no doubt when she was still younger she had actually *been* a horse. The *falling down* was related to a memory from very early childhood of the seventeen year-old son of the house-porter who had fallen down in the street in an epileptic fit and been brought home in a carriage. She had of course only *heard* about this, but the idea of epileptic fits (of the '*falling sickness*') had obtained a hold on her imagination and had later influenced the form taken by her own hysterical attacks. - If a woman dreams of falling, it almost invariably has a sexual sense: she is imagining herself as a '*fallen woman*'. The present dream in particular scarcely left any room for doubt, since the place where my patient fell was the Graben, a part of Vienna notorious as a promenade for prostitutes. The *shopping-basket* [*Korb*] led to more than one interpretation. It reminded her of the numerous *rebuffs* [*Körbe*] which she had dealt out to her suitors, as well as of those which she complained of having later received herself. This also connected with the fact that *no one helped her up*, which she herself explained as a rebuff. The *shopping-basket* further reminded her of phantasies which had already come up in her analysis, in which she was married far beneath her and had to go marketing herself. And lastly it might serve as the mark of a servant. At this point further childhood recollections emerged. First, of a cook who had been dismissed for stealing, and who had *fallen on her knees* and begged to be forgiven. She herself had been twelve at the time. Then, of a housemaid who had been dismissed on account of a love-affair with the family *coachman* (who incidentally married her subsequently). Thus this memory was also one of the sources of the coachmen (*drivers*) in the dream (who, in contradistinction to the actual coachman, failed to raise the fallen woman). There remained to be explained the fact of the basket being *thrown in after her* and *through the window*. This reminded her of *handing in* luggage to be *sent off* by rail, of the country custom of lovers climbing in through their sweethearts' *window* and of other little episodes from her life in the country: how a gentleman had thrown some *blue plums* to a lady *through the window* of her room, and how her own younger sister had been scared by the village idiot looking in *through her window*. An obscure memory from her tenth year then began to emerge, of a nurse in the country who had had love-scenes (which the girl might have seen something of) with one of the servants in the house and who, along with her lover, had been *sent off, thrown out* (the opposite of the dream-image '*thrown in*') - a story that we had already approached from several other directions. A servant's luggage or trunk is referred to contemptuously in Vienna as '*seven plums*': 'pack up your seven plums and out you go!'

My records naturally include a large collection of patients' dreams the analysis of which led to obscure or entirely forgotten impressions of childhood, often going back to the first three years of life. But it would be unsafe to apply any conclusions drawn from them to dreams in general. The persons concerned were in every instance neurotics and in particular hysterics; and it is possible that the part played by childhood scenes in their dreams might be determined by the nature of their neurosis and not by the nature of dreams. Nevertheless, in analysing my own dreams - and, after all, I am not doing so on account of any gross pathological symptoms - it happens no less frequently that in the latent content of a dream I come unexpectedly upon a scene from childhood, and that all at once a whole series of my dreams link up with the associations branching out from some experience of my childhood. I have already given some instances of this, and I shall have others to give in a variety of connections. I cannot, perhaps, bring this section to a better close than by reporting one or two dreams of mine in which recent occasions and long-forgotten experiences of childhood came together as sources of the dream.

I

Tired and hungry after a journey, I went to bed, and the major vital needs began to announce their presence in my sleep; I dreamt as follows:

I went into a kitchen in search of some pudding. Three women were standing in it; one of them was the hostess of the inn and was twisting something about in her hands, as though she were making Knödel. She answered that I must wait until she was ready. (These were not definite spoken words.) I felt impatient and went off with a sense of injury. I put on an overcoat. But the first I tried on was too long for me. I took it off, rather surprised to find it was trimmed with fur. A second one that I put on had had a long strip with a Turkish design let into it. A stranger with a long face and a short pointed beard came up and tried to prevent my putting it on, saying it was his. I showed him then that it was embroidered all over with a Turkish pattern. He asked: 'What have the Turkish (designs, stripes . . .) to do with you?' But then we became quite friendly with each other.

When I began analysing this dream, I thought quite unexpectedly of the first novel I ever read (when I was thirteen, perhaps); as a matter of fact I began at the end of the first volume. I have never known the name of the novel or of its author; but I have a vivid memory of its ending. The hero went mad and kept calling out the names of the three women who had brought the greatest happiness and sorrow into his life. One of these names was *Pélagie*. I still had no notion what this recollection was going to lead to in the analysis. In connection with the three women I thought of the three Fates who spin the destiny of man, and I knew that one of the three women - the inn-hostess in the dream - was the mother who gives life, and furthermore (as in my own case) gives the living creature its first nourishment. Love and hunger, I reflected, meet at a woman's breast. A young man who was a great admirer of feminine beauty was talking once - so the story went - of the good-looking wet-nurse who had suckled him when he was a baby: 'I'm sorry', he remarked, 'that I didn't make a better use of my opportunity.' I was in the habit of quoting this anecdote to explain the factor of 'deferred action' in the mechanism of the psychoneuroses. - One of the Fates, then, was rubbing the palms of her hands together as though she was making dumplings: a queer occupation for a Fate, and one that cried out for an explanation. This was provided by another and earlier memory of my childhood. When I was six years old and was given my first lessons by my mother, I was expected to believe that we were all made of earth and must therefore return to earth. This did not suit me and I expressed doubts of the doctrine. My mother thereupon rubbed the palms of her hands together - just as she did in making dumplings, except that there was no dough between them - and showed me the blackish scales of *epidermis* produced by the friction as a proof that we were made of earth. My astonishment at this ocular demonstration knew no bounds and I acquiesced in the belief which I was later to hear expressed in the words: '*Du bist der Natur einen Tod schuldig.*' ['Thou owest Nature a death.']* So they really were Fates that I found in the kitchen when I went into it - as I had so often done in my childhood when I was hungry, while my mother, standing by the fire, had admonished me that I must wait till dinner was ready. - And now for the dumplings - the *Knöde!* One at least of my teachers at the University - and precisely the one to whom I owe my histological knowledge (for instance of the *epidermis*) - would infallibly be reminded by the name *Knödl* of a person against whom he had been obliged to take legal action for *plagiarizing* his writings. The idea of plagiarizing - of appropriating whatever one can, even though it belongs to someone else - clearly led on to the second part of the dream, in which I was treated as though I were the thief who had for some time carried on his business of stealing overcoats in the lecture-rooms. I had written down the word 'plagiarizing', without thinking about it, because it occurred to me; but now I noticed that it could form a bridge [*Brücke*] between different pieces of the dream's manifest content. A chain of associations (*Pélagie* - *plagiarizing* - *plagiostomes*² or sharks [*Haifische*] - *a fish's swimming-bladder* [*Fischblase*]) connected the old novel with the case of Knödl and with the overcoats, which clearly referred to implements used in sexual technique. (Cf. Maury's alliterative dreams.) No doubt it was a very far-fetched and senseless chain of thought; but I could never have constructed it in waking life unless it had already been constructed by the dream-work. And, as though the need to set up forced connections regarded *nothing* as sacred, the honoured name of Brücke (cf. the verbal *bridge* above) reminded me of the Institute in which I spent the happiest hours of my student life, free from all other desires -

So wird's Euch an der Weisheit *Brüsten*
Mit jedem Tage mehr gelüsten³

- in complete contrast to the desires which were now *plaguing* me in my dreams. Finally there came to mind another much respected teacher - his name, Fleischl ['*Fleisch*' = 'meat'], like Knödl, sounded like something to eat - and a distressing scene in which *scales of epidermis* played a part (my mother and the inn-hostess) as well as *madness* (the novel) and a drug from the dispensary which removes *hunger*: cocaine.

¹ Both of the emotions that were attached to these childhood scenes - astonishment and submission to the inevitable - had occurred in a dream which I had had shortly before this one and which had first reminded me of this event in my childhood.

² I have deliberately avoided enlarging upon the plagiostomes; they reminded me of an unpleasant occasion on which I had disgraced myself in connection with this same University teacher.

³ ['Thus, at the *breasts* of Wisdom clinging,
Thou'lt find each day a greater rapture bringing.']

I might pursue the intricate trains of thought further along these lines and explain fully the part of the dream which I have not analysed; but I must desist at this point because the personal sacrifice demanded would be too great. I will only pick out one thread, which is qualified to lead us straight to one of the dream-thoughts underlying the confusion. The stranger with the long face and pointed beard who tried to prevent my putting on the overcoat bore the features of a shop-keeper at Spalato from whom my wife had bought a quantity of *Turkish* stuffs. He was called Popovic, an equivocal name, on which a humorous writer, Stettenheim, has already made a suggestive comment: 'He told me his name and blushing pressed my hand.' Once again I found myself misusing a name, as I already had done with Pélagie, Knödl, Brücke and Fleischl. It could scarcely be denied that playing about with names like this was a kind of childish naughtiness. But if I indulged in it, it was as an act of retribution; for my own name had been the victim of feeble witticisms like these on countless occasions. Goethe, I recalled, had remarked somewhere upon people's sensitiveness about their names: how we seem to have grown into them like our *skin*. He had said this *à propos* of a line written on his name by Herder:

'Der du von Göttern abstammst, von Gothen oder vom Kote.' -¹

'So seid ihr Götterbilder auch zu Staub.' ²

I noticed that my digression on the subject of the misuse of names was only leading up to this complaint. But I must break off here. - My wife's purchase made at Spalato reminded me of another purchase, made at Cattaro, which I had been too cautious over, so that I had lost an opportunity of making some nice acquisitions. (Cf. the neglected opportunity with the wet-nurse.) For one of the thoughts which my hunger introduced into the dream was this: 'One should never neglect an opportunity, but always take what one can even when it involves doing a small wrong. One should never neglect an opportunity, since life is short and death inevitable.' Because this lesson of '*carpe diem*' had among other meanings a sexual one, and because the desire it expressed did not stop short of doing wrong, it had reason to dread the censorship and was obliged to conceal itself behind a dream. All kinds of thoughts having a *contrary* sense then found voice: memories of a time when the dreamer was content with *spiritual* food, restraining thoughts of every kind and even threats of the most revolting sexual punishments.

¹ ['Thou who art the offspring of gods or of Goths or of dung']

² ['So you too, divine figures, have turned to dust!']

II

The next dream calls for a rather long preamble:

I had driven to the Western Station to take the train for my summer holiday at Aussee, but had arrived on the platform while an earlier train, going to Ischl, was still standing in the station. There I had seen Count Thun who was once again travelling to Ischl for an audience with the Emperor. Though it was raining, he had arrived in an open carriage. He had walked straight in through the entrance for the Local Trains. The ticket inspector at the gate had not recognized him and had tried to take his ticket, but he had waved the man aside with a curt motion of his hand and without giving any explanation. After the train for Ischl had gone out, I ought by rights to have left the platform again and returned to the waiting room; and it had cost me some trouble to arrange matters so that I was allowed to stop on the platform. I had passed the time in keeping a look-out to see if anyone came along and tried to get a reserved compartment by exercising some sort of 'pull'. I had intended in that case to make a loud protest: that is to say to claim equal rights. Meantime I had been humming a tune to myself which I recognized as Figaro's aria from *Le Nozze di Figaro*:

Se vuol ballare, signor contino,
Se vuol ballare, signor contino,
Il chitarino le suonerò¹

(It is a little doubtful whether anyone else would have recognized the tune.)

¹ [If my Lord Count is inclined to go dancing,
If my Lord Count is inclined to go dancing,
I'll be quite ready to play him a tune . . .]

The whole evening I had been in high spirits and in a combative mood. I had chaffed my waiter and my cab-driver - without, I hope, hurting their feelings. And now all kinds of insolent and revolutionary ideas were going through my head, in keeping with Figaro's words and with my recollections of Beaumarchais' comedy which I had seen acted by the *Comédie française*. I thought of the phrase about the great gentlemen who had taken the trouble to be born, and of the *droit du Seigneur* which Count Almaviva tried to exercise over Susanna. I thought, too, of how our malicious opposition journalists made jokes over Count Thun's name, calling him instead 'Count Nichtsthun'. Not that I envied him. He was on his way to a difficult audience with the Emperor, while I was the real Count Do-nothing -(just off on my holidays. There followed all sorts of enjoyable plans for the holidays. At this point a gentleman came on to the platform whom I recognized as a Government invigilator at medical examinations, and who by his activities in that capacity had won the flattering nickname of 'Government bedfellow'. He asked to be given a first-class half-compartment to himself in virtue of his official position, and I heard one railwayman saying to another: 'Where are we to put the gentleman with the half first-class ticket?' This, I thought to myself, was a fine example of privilege; after all I had paid the full first-class fare. And I did in fact get a compartment to myself, but not in a corridor coach, so that there would be no lavatory available during the night. I complained to an official without any success; but I got my own back on him by suggesting that he should at all events have a hole made in the floor of the compartment to meet the possible needs of passengers. And in fact I did wake up at a quarter to three in the morning with a pressing need to micturate, having had the following dream:

A crowd of people, a meeting of students. - A count (Thun or Taaffe) was speaking. He was challenged to say something about the Germans, and declared with a contemptuous gesture that their favourite flower was a colt's foot, and put some sort of dilapidated leaf - or rather the crumpled skeleton of a leaf - into his buttonhole. I fired up - so I fired up,¹ though I was surprised at my taking such an attitude.

(Then, less distinctly:) It was as though I was in the Aula, the entrances were cordoned off and we had to escape. I made my way through a series of beautifully furnished rooms, evidently ministerial or public apartments, with furniture upholstered in a colour between brown and violet; at last I came to a corridor, in which a housekeeper was sitting, an elderly stout woman. I avoided speaking to her, but she evidently thought I had a right to pass, for she asked whether she should accompany me with the lamp. I indicated to her, by word or gesture, that she was to stop on the staircase; and I felt I was being very cunning in thus avoiding inspection at the exit. I got downstairs and found a narrow and steep ascending path, along which I went.

(Becoming indistinct again) . . . It was as though the second problem was to get out of the town, just as the first one had been to get out of the house. I was driving in a cab and had ordered the driver to drive me to a station. 'I can't drive with you along the railway-line itself', I said, after he had raised some objection, as though I had overtired him. It was as if I had already driven with him for some of the distance one normally travels by train. The stations were cordoned off. I wondered whether to go to Krems or Znaim, but reflected that the Court would be in residence there, so I decided in favour of Graz, or some such place. I was now sitting in the compartment, which was like a carriage on the Stadtbahn; and in my buttonhole I had a peculiar plaited, long-shaped object, and beside it some violet-brown violets made of a stiff material. This greatly struck people. (At this point the scene broke off.)

Once more I was in front of the station, but this time in the company of an elderly gentleman. I thought of a plan for remaining unrecognized; and then saw that this plan had already been put into effect. It was as though thinking and experiencing were one and the same thing. He appeared to be blind, at all events with one eye, and I handed him a male glass urinal (which we had to buy or had bought in town). So I was a sick-nurse and had to give him the urinal because he was blind. If the ticket-collector were to see us like that, he would be certain to let us get away without noticing us. Here the man's attitude and his micturating penis appeared in plastic form. (This was the point at which I awoke, feeling a need to micturate.)

The dream as a whole gives one the impression of being in the nature of a phantasy in which the dreamer was carried back to the Revolutionary year 1848. Memories of that year had been recalled to me by the Jubilee in 1898, as well as by a short trip which I had made to *the Wachau*, in the course of which I had visited Emmersdorf,² the place of retirement of the student-leader Fischhof, to whom certain elements in the manifest content of the dream may allude. My associations then led me to England and to my brother's house there. He used often to tease his wife with the words 'Fifty Years Ago' (from the title of one of Lord Tennyson's poems), which his children used then to correct to '*fifteen years ago*'. This revolutionary phantasy, however, which was derived from ideas aroused in me by seeing Count Thun, was like the façade of an Italian church in having no organic relation with the structure lying behind it. But it differed from those façades in being disordered and full of gaps, and in the fact that portions of the interior construction had forced their way through into it at many points.

¹ This repetition crept into my record of the dream, apparently through inadvertence. I have let it stand, since the analysis showed that it was significant.

² (Footnote added 1925 :) This is a mistake, but not a slip this time. I only learnt later that the Emmersdorf in the Wachau is not to be identified with the place of the same name which was the refuge of the revolutionary leader Fischhof.

The first situation in the dream was an amalgam of several scenes, which I can separate out. The insolent attitude adopted by the Count in the dream was copied from a scene at my secondary school when I was *fifteen years* old. We had hatched a conspiracy against an unpopular and ignorant master, the moving spirit of which had been one of my school-fellows who since those days seemed to have taken *Henry VIII of England* as his model. The leadership in the chief assault was allotted to me, and the signal for open revolt was a discussion on the significance of the Danube to Austria (cf. *the Wachau*). One of our fellow-conspirators had been the only aristocratic boy in the class, who, on account of his remarkable length of limb, was called 'the Giraffe'. He was standing up, like the Count in my dream, having been taken to task by the school tyrant, the *German language* master. The *favourite flower* and the *putting into his buttonhole* of something in the nature of a flower (which last made me think of some orchids which I had brought the same day for a woman friend and also of a rose of Jericho) were a striking reminder of the scene in one of Shakespeare's historical plays which represented the beginning of the Wars of the *Red and White Roses*. (The mention of *Henry VIII* opened the way to this recollection.) - From there it was only a short step to red and white carnations. (Two little couplets, one in *German* and the other in *Spanish*, slipped into the analysis at this point:

Rosen, Tulpen, Nelken,
alle Blumen welken.¹

Isabelita, no llores,
que se marchitan las flores.²

The appearance of a *Spanish* couplet led back to *Figaro*.) Here in Vienna white carnations had become an emblem of anti-semitism, and red ones of the Social Democrats. Behind this lay a recollection of a piece of anti-semitic provocation during a railway journey in the lovely Saxon countryside (cf. *Anglo-Saxon*). -The third scene which contributed to the formation of the first situation in the dream dated from my early student days. There was a discussion in a *German* students' club on the relation of philosophy to the natural sciences. I was a green youngster, full of materialistic theories, and thrust myself forward to give expression to an extremely one-sided point of view. Thereupon someone who was my senior and my superior, someone who has since then shown his ability as a leader of men and an organizer of large groups (and who also, incidentally, bears a name derived from the Animal Kingdom), stood up and gave us a good talking-to: he too, he told us, had fed swine in his youth and returned repentant to his father's house. *I fired up* (as I did in the dream) and replied boorishly that since I now knew that he had fed *swine* in his youth I was no longer *surprised* at the tone of his speeches. (In the dream I was *surprised* at my German-nationalist attitude.) There was a general uproar and I was called upon from many sides to withdraw my remarks, but I refused to do so. The man I had insulted was too sensible to look upon the incident as a *challenge*, and let the affair drop.

¹ ['Roses, tulips, carnations: every flower fades.']

² ['*Isabelita*, do not weep because the flowers fade.']

The remaining elements of this first situation in the dream were derived from deeper layers. What was the meaning of the Count's pronouncement about colt's foot? To find the answer, I followed a train of associations: colt's foot ['*Huflattich*', literally 'hoof lettuce'] - lettuce - salad - dog-in-the-manger ['*Salathund*', literally 'salad dog']. Here was a whole collection of terms of abuse: 'Gir-affe' ['*Affe*' is the German for 'ape'], 'swine', 'dog' - and I could have arrived at 'donkey' if I had made a detour through another name and insulted yet another academic teacher. Moreover, I translated 'colt's foot' - whether rightly or wrongly I could not tell - by the French '*pisse-en-lit*'. This information was derived from Zola's *Germinal*, in which a child was told to pick some of that plant for salad. The French word for 'dog' - '*chien*' - reminded me of the major function ('*chier*' in French, compared with '*pisser*' for the minor one). Soon, I thought, I should have collected examples of impropriety in all three states of matter - solid, liquid and gaseous; - for this same book, *Germinal*, which had plenty to do with the approaching revolution, contained an account of a very peculiar sort of competition - for the production of a gaseous excretion known by the name of '*flatus*'.¹ I now saw that the path leading to *flatus* had been prepared far ahead: from *flowers*, through the *Spanish* couplet, *Isabelita, Isabella* and Ferdinand, *Henry VIII, English* history, and the Armada which sailed against *England*, after whose defeat a medal was struck, bearing the inscription '*Flavit et dissipati sunt*'², since the storm-blast had scattered the Spanish fleet. I had thought, half seriously, of using those words as the heading to the chapter on 'Therapy', if ever I got so far as producing a detailed account of my theory and treatment of hysteria.

¹ Not in fact in *Germinal* but in *La terre*: a mistake which I only observed after I had completed the analysis. - Notice the occurrence of the same letters in '*Huflattich*' ['colt's foot'] and '*flatus*'.

² [Footnote added 1925:] An unsolicited biographer, Dr. Fritz Wittels has charged me with having omitted the name of Jehovah from the above motto. [Added 1930:] The English medallion bears the deity's name in Hebrew lettering on a cloud in the background. It is so placed that it can be taken as being part either of the design or of the inscription.

Turning now to the second episode of the dream, I am unable to deal with it in such detail - out of consideration for the censorship. For I was putting myself in the place of an exalted personage of those revolutionary times, who also had an adventure with an eagle [*Adler*] and is said to have suffered from incontinence of the bowels, and so on. I thought to myself that *I should not be justified in passing* the censorship at this point, even though the greater part of the story was told me by a Hofrat (a *consiliarius aulicus* [court councillor] - cf. *Aula*). The series of public rooms in the dream were derived from His Excellency's saloon carriage, of which I had succeeded in getting a glimpse. But the 'rooms' [*Zimmer*] also meant 'women' [*Frauenzimmer*], as is often the case in dreams - in this instance 'public women'. In the figure of the housekeeper I was showing my lack of gratitude towards a witty elderly lady and ill repaying her hospitality and the many good stories that I heard while I was stopping in her house. -The allusion to the lamp went back to Grillparzer, who introduced a charming episode of a similar kind, which he had actually experienced, into his tragedy about Hero and Leander, *Des Meeres und der Liebe Wellen* ['The Waves of the Sea and of Love'] - the Armada and the *storm*.¹

¹ [Footnote added 1911:] In an interesting paper, Silberer (1910) has tried to show from this part of my dream that the dream-work can succeed in reproducing not only the latent dream-thoughts but also the psychical processes that take place during the formation of dreams. (This is what he terms 'the functional phenomenon'.) [Added 1914:] But he is, I think, overlooking the fact that 'the psychical processes that take place during the formation of dreams' were, like the rest, part of the *material* of my thoughts. In this boastful dream I was evidently proud of having discovered those processes.

I must also refrain from any detailed analysis of the two remaining episodes of the dream. I will merely pick out the elements leading to the two childhood scenes on whose account alone I embarked upon a discussion of this dream. It will rightly be suspected that what compels me to make this suppression is sexual material; but there is no need to rest content with this explanation. After all, there are many things which one has to keep secret from other people but of which one makes no secret to oneself; and the question here is not as to why I am obliged to conceal the solution but as to the motives for the *internal* censorship which hid the true content of the dream from myself. I must therefore explain that the analysis of these three episodes of the dream showed that they were impertinent boastings, the issue of an absurd megalomania which had long been suppressed in my waking life and a few of whose ramifications had even made their way into the dream's manifest content (e. g. '*I felt I was being very cunning*'), and which incidentally accounted for my exuberant spirits during the evening before I had the dream. The boasting extended to all spheres; for instance, the mention of *Graz* went back to the slang phrase 'What's the price of Graz? ', which expresses the self-satisfaction of a person who feels extremely well-off. The first episode of the dream may also be included among the boastings by anyone who will bear in mind the great Rabelais' incomparable account of the life and deeds of Gargantua and his son Pantagruel.

Here is the material relating to the two childhood scenes which I have promised my readers. I had bought a new trunk for the journey, of a *brownish violet* colour. This colour appears more than once in the dream: the *violet-brown violets made of a stiffish material* and beside them a thing known as a '*Mädchenfänger*' ['girl-catcher'] - and the furniture in the ministerial apartments. It is commonly believed by children that *people are struck* by anything new. The following scene from my childhood has been described to me, and my memory of the description has taken the place of my memory of the scene itself. It appears that when I was two years old I still occasionally *wetted the bed*, and when I was reproached for this I *consoled* my father by promising to buy him a nice *new red* bed in N., the nearest town of any size. This was the origin of the parenthetical phrase in the dream to the effect that *we bought or had to buy the urinal* in town: one must keep one's promises. (Notice, too, the juxtaposition in symbolism of the male urinal and the female trunk or box.) This promise of mine exhibited all the megalomania of childhood. We have already come across the significant part played in dreams by children's difficulties in connection with micturition (cf. the dream reported on p. 685). We have also learned from the psycho-analysis of neurotic subjects the intimate connection between bed-wetting and the character trait of ambition.

When I was seven or eight years old there was another domestic scene, which I can remember very clearly. One evening before going to sleep I disregarded the rules which modesty lays down and obeyed the calls of nature in my parents' bedroom while they were present. In the course of his reprimand, my father let fall the words: 'The boy will come to nothing.' This must have been a frightful blow to my ambition, for references to this scene are still constantly recurring in my dreams and are always linked with an enumeration of my achievements and successes, as though I wanted to say: 'You see, I *have* come to something.' This scene, then, provided the material for the final episode of the dream, in which - in revenge, of course - the roles were interchanged. The older man (clearly my father, since his blindness in one eye referred to his unilateral glaucoma¹) was now micturating in front of me, just as I had in front of him in my childhood. In the reference to his glaucoma I was reminding him of the cocaine, which had helped him in the operation, as though I had in that way kept my promise. Moreover, I was making fun of him; I had to hand him the urinal because he was blind, and I revelled in allusions to my discoveries in connection with the theory of hysteria, of which I felt so proud.²

¹ There is another interpretation. He was one-eyed like Odin the father-god. - *Odhins Trost*. - The consolation I offered him in the first childhood scene of buying him a new bed.

² Here is some further interpretative material. Handing him the glass reminded me of the story of the peasant at the optician's, trying glass after glass and still not being able to read. - (Peasant-catcher [*Bauerfänger*, 'sharper': girl-catcher [*Mädchenfänger*] in the preceding episode of the dream.) - The way in which the father in Zola's *La terre* was treated among the peasants after he had grown feeble-minded. - The tragic requital that lay in my father's soiling his bed like a child during the last days of his life; hence my appearance in the dream as a *sick-nurse*. - 'Here it was as though thinking and experiencing were one and the same thing.' This recalled a strongly revolutionary literary play by Oskar Panizza, in which God the Father is ignominiously treated as a paralytic old man. In his case will and deed were represented as one and the same thing, and he had to be restrained from cursing and swearing by one of his archangels, a kind of Ganymede, because his imprecations would be promptly fulfilled. - My making *plans* was a reproach against my father dating from a later period. And indeed the whole rebellious content of the dream, with its *lèse majesté* and its derision of the higher authorities, went back to rebellion against my father. A Prince is known as the father of his country; the father is the oldest, first, and for children the only authority, and from his autocratic power the other social authorities have developed in the course of the history of human civilization - except in so far as the 'matriarchy' calls for a qualification of this assertion. - The phrase '*thinking and experiencing were one and the same thing*' had a reference to the explanation of hysterical symptoms, and the '*male urinal*' belonged in the same connection. I need not explain to a Viennese the principle of the '*Gschnas*'. It consists in constructing what appear to be rare, and precious objects out of trivial and preferably comic and worthless materials (for instance, in making armour out of saucépans, wisps of straw and dinner rolls) - a favourite pastime at bohemian parties here in Vienna. I had observed that this is precisely what hysterical subjects do: alongside what has really happened to them, they unconsciously build up frightful or perverse imaginary events which they construct out of the most innocent and everyday material of their experience. It is to these phantasies that their symptoms are in the first instance attached and not to their recollections of real events, whether serious or equally innocent. This revelation had helped me over a number of difficulties and had given me particular pleasure. What made it possible for me to refer to this by means of the dream-element of the '*male urinal*' was as follows. I had been told that at the latest '*Gschnas*'-night a poisoned chalice belonging to Lucrezia Borgia had been exhibited; its central and principal constituent had been a *male urinal* of the type used in hospitals.

The two scenes of micturition from my childhood were in any case closely linked to the topic of megalomania; but their emergence while I was travelling to Aussee was further assisted by the chance circumstance that there was no lavatory attached to my compartment and that I had reason to anticipate the predicament which in fact arose in the morning. I awoke with the sensations of a physical need. One might, I think, be inclined to suppose that these sensations were the actual provoking agent of the dream; but I would prefer to take another view, namely that the desire to micturate was only called up by the dream-thoughts. It is quite unusual for me to be disturbed in my sleep by physical needs of any kind, especially at the hour at which I awoke on this occasion - a quarter to three in the morning. And I may meet a further objection by remarking that upon other journeys under more comfortable conditions I have scarcely ever felt a need to micturate when I have woken up early. But in any case it will do no harm to leave the point unresolved.

My experiences in analysing dreams have drawn my attention to the fact that trains of thought reaching back to earliest childhood lead off even from dreams which seem at first sight to have been completely interpreted, since their sources and instigating wish have been discovered without difficulty. I have therefore been compelled to ask myself whether this characteristic may not be a further essential precondition of dreaming. Stated in general terms, this would imply that every dream was linked in its manifest content with recent experiences and in its latent content with the most ancient experiences. And I have in fact been able to show in my analysis of hysteria that these ancient experiences have remained recent in the proper sense of the word up to the immediate present. It is still extremely hard to demonstrate the truth of this suspicion; and I shall have to return in another connection (Chapter VII) to a consideration of the probable part played by the earliest experiences of childhood in the formation of dreams.

Of the three characteristics of memory in dreams enumerated at the beginning of this chapter, one - the preference for non-essential material in the content of dreams - has been satisfactorily cleared up by being traced back to dream-distortion. We have been able to confirm the existence of the other two - the emphasis upon recent and upon infantile material - but we have not been able to account for them on the basis of the motives that lead to dreaming. These two characteristics inclusion of both recent and infantile material, whose explanation and appreciation remain to be discovered, must be kept in mind. Their proper place must be looked for elsewhere - either in the psychology of the state of sleep or in the discussion of the structure of the mental apparatus upon which we shall later embark, after we have learnt that the interpretation of dreams is like a window through which we can get a glimpse of the interior of that apparatus.

There is, however, another inference following from these last dream-analyses to which I will draw attention at once. Dreams frequently seem to have more than one meaning. Not only, as our examples have shown, may they include several wish-fulfilments one alongside the other; but a succession of meanings or wish-fulfilments may be superimposed on one another, the bottom one being the fulfilment of a wish dating from earliest childhood. And here again the question arises whether it might not be more correct to assert that this occurs 'invariably' rather than 'frequently'.¹

¹ [*Footnote added 1914:*] The fact that the meanings of dreams are arranged in superimposed layers is one of the most delicate, though also one of the most interesting, problems of dream-interpretation. Anyone who forgets this possibility will easily go astray and be led into making untenable assertions upon the nature of dreams. Yet it is still a fact that far too few investigations have been made into this matter. Hitherto the only thorough piece of research has been Otto Rank's into the fairly regular stratification of symbols in dreams provoked by pressure of the bladder.

(C)

THE SOMATIC SOURCES OF DREAMS

If one tries to interest an educated layman in the problem of dreams and, with that end in view, asks him what in his opinion are the sources from which they arise, one finds as a rule that he feels confident of possessing the answer to this part of the question. He thinks at once of the effects produced on the construction of dreams by digestive disturbances or difficulties - 'dreams come from indigestion' -, by postures accidentally assumed by the body and by other small incidents during sleep. It never seems to occur to him that when all these factors have been taken into account anything is left over that needs explaining.

I have already discussed at length in the opening chapter (Section C) the part assigned by scientific writers to somatic sources of stimulation in the formation of dreams; so that here I need only recall the results of that enquiry. We found that three different kinds of somatic sources of stimulation were distinguished: objective sensory stimuli arising from external objects, internal states of excitation of the sense organs having only a subjective basis, and somatic stimuli derived from the interior of the body . We noticed moreover that the authorities were inclined to push into the background, or to exclude entirely, any possible *psychical* sources of dreams, as compared with these somatic stimuli (cf. p. 552). In our examination of the claims made on behalf of somatic sources of stimulation we arrived at the following conclusions. The significance of *objective* excitations of the sense organs (consisting partly of chance stimuli during sleep and partly of excitations such as cannot fail to impinge even upon a sleeping mind) is established from numerous observations and has been experimentally confirmed (cf. p. 538). The part played by *subjective* sensory excitations seems to be demonstrated by the recurrence in dreams of hypnagogic sensory images (cf. p. 543 f.). And lastly it appears that, though it is impossible to prove that the images and ideas occurring in our dreams can be traced back to *internal* somatic stimuli to the extent to which this has been asserted to be the case, nevertheless this origin finds support in the universally recognized influence exercised upon our dreams by states of excitation in our digestive, urinary and sexual organs.

It would appear, then, that 'nervous stimulation' and 'somatic stimulation' are the somatic sources of dreams - that is to say, according to many writers, their sole source.

On the other hand, we have already found a number of doubts expressed, which seemed to imply a criticism, not indeed of the *correctness*, but of the *adequacy* of the theory of somatic stimulation.

However secure the supporters of this theory might feel in its factual basis - especially as far as accidental and external nervous stimuli are concerned, since these can be traced in the content of dreams without any trouble at all - not one of them could fail to perceive that it is impossible to attribute the wealth of ideational material in dreams to external nervous stimuli alone. Miss Mary Whiton Calkins (1893, 312) examined her own and another person's dreams for six weeks with this question in mind. She found that in only 13.2 per cent and 6.7 per cent of them respectively was it possible to trace the element of external sense-perception; while only two cases in the collection were derivable from organic sensations. Here we have statistical confirmation of what I had been led to suspect from a hasty survey of my own experiences.

It has often been proposed to separate off 'dreams due to nervous stimulation' from other forms of dreams as a sub-species that has been thoroughly investigated. Thus Spitta divides dreams into 'dreams due to nervous stimulation' and 'dreams due to association'. This solution was, however, bound to remain unsatisfactory so long as it was impossible to demonstrate the link between the somatic sources of a dream and its ideational content. Thus, in addition to the first objection - the insufficient frequency of external sources of stimulation - there was a second one - the insufficient explanation of dreams afforded by such sources. We have a right to expect the supporters of this theory to give us explanations of two points; first, why it is that the external stimulus of a dream is not perceived in its true character but is invariably misunderstood (Cf. the alarm-clock dreams on p. 541 f.); and secondly, why it is that the reaction of the perceiving mind to these misunderstood stimuli should lead to results of such unpredictable variety.

By way of answer to these questions, Strümpell (1877, 108 f.) tells us that, because the mind is withdrawn from the external world during sleep, it is unable to give a correct interpretation of objective sensory stimuli and is obliged to construct illusions on the basis of what is in many respects an indeterminate impression. To quote his own words: 'As soon as a sensation or complex of sensations or a feeling or a psychical process of any kind arises in the mind during sleep as a result of an external or internal nervous stimulus and is perceived by the mind, that process calls up sensory images from the circle of experiences left over in the mind from the waking state - that is to say, earlier perceptions - which are either bare or accompanied by their appropriate psychical values. The process surrounds itself, as it were, with a larger or smaller number of images of this kind and through them the impression derived from the nervous stimulus acquires its psychical value. We speak here (just as we usually do in the case of waking behaviour) of the sleeping mind "interpreting" the impressions made by the nervous stimulus. The outcome of this interpretation is what we describe as a "dream due to nervous stimulation", that is, a dream whose components are determined by a nervous stimulus producing its psychical effects in the mind according to the laws of reproduction.'

Wundt is saying something essentially identical with this theory when he asserts that the ideas occurring in dreams are derived, for the most part at least, from sensory stimuli, including especially coenaesthetic sensations, and are for that reason mainly imaginative illusions and probably only to a small extent pure mnemonic ideas intensified into hallucinations. Strümpell (1877, 84) has hit upon an apt simile for the relation which subsists on this theory between the contents of a dream and its stimuli, when he writes that 'it is as though the ten fingers of a man who knows nothing of music were wandering over the keys of a piano'. Thus a dream is not, on this view, a mental phenomenon based on psychical motives, but the outcome of a physiological stimulus which is expressed in psychical symptoms because the apparatus upon which the stimulus impinges is capable of no other form of expression. A similar presupposition also underlies, for instance, the famous analogy by means of which Meynert attempted to explain obsessive ideas: the analogy of a clock-face on which certain figures stand out by being more prominently embossed than the rest.

However popular the theory of the somatic stimulation of dreams may have become and however attractive it may seem, its weak point is easily displayed. Every somatic dream stimulus which requires the sleeping mental apparatus to interpret it by the construction of an illusion may give rise to an unlimited number of such attempts at interpretation - that is to say, it may be represented in the content of the dream by an immense variety of ideas.¹ But the theory put forward by Strümpell and Wundt is incapable of producing any motive governing the relation between an external stimulus and the dream-idea chosen for its interpretation - is incapable, that is, of explaining what Lipps (1883, 170) describes as the 'remarkable choice often made' by these stimuli 'in the course of their productive activity'. Objections have further been raised against the presupposition upon which the whole theory of illusion is based - the presupposition that the sleeping mind is incapable of recognizing the true nature of objective sensory stimuli. Burdach, the physiologist, showed us long ago that even in sleep the mind is very well able to interpret correctly the sense impressions that reach it and to react in accordance with that correct interpretation; for he recalled the fact that particular sense impressions which seem important to the sleeper can be excepted from the general neglect to which such impressions are subjected during sleep (as in the case of a nursing mother or wet-nurse and her charge), and that a sleeper is much more certain to be woken by the sound of his own name than by any indifferent auditory impression - all of which implies that the mind distinguishes between sensations during sleep (cf. p. 562). Burdach went on to infer from these observations that what we must presume during the state of sleep is not an *incapacity to interpret* sensory stimuli but a *lack of interest* in them. The same arguments which were used by Burdach in 1830 were brought forward once more without any modifications by Lipps in 1883 in his criticism of the theory of somatic stimulation. Thus the mind seems to behave like the sleeper in the anecdote. When someone asked him if he was asleep, he replied 'No'. But when his questioner went on to say; 'Then lend me ten florins', he took refuge in a subterfuge and replied: 'I'm asleep.'

¹ [Footnote added 1914]: Mourly Vold has produced a two-volume work containing detailed and precise reports of a series of experimentally produced dreams. I should recommend a study of this work to anyone who wishes to convince himself of how little light is thrown on the content of individual dreams by the conditions of the experiments described in it and of how little help in general is afforded by such experiments towards an understanding of the problems of dreams.

The inadequacy of the theory of the somatic stimulation of dreams can be demonstrated in other ways. Observation shows that external stimuli do not necessarily compel me to dream, even though such stimuli appear in the content of my dream when and if I do dream. Supposing, let us say, that I am subjected to a tactile stimulus while I am asleep. A variety of different reactions are then open to me. I may disregard it, and when I wake up I may find, for instance, that my leg is uncovered or that there is some pressure on my arm; pathology provides very numerous instances in which various powerfully exciting sensory and motor stimuli can remain without effect during sleep. Or again, I may be aware of the sensation in my sleep - I may be aware of it, as one might say, 'through' my sleep -(which is what happens as a rule in the case of painful stimuli) but without my weaving the pain into a dream. And thirdly, I may react to the stimulus by waking up so as to get rid of it.¹ It is only as a fourth possibility that the nervous stimulus may cause me to dream. Yet the other possibilities are realized at least as frequently as this last one of constructing a dream. And this could not happen unless the motive for dreaming lay *elsewhere than in somatic sources of stimulation*.

Certain other writers - Scherner and Volkelt, the philosopher, who adopted Scherner's views - formed a just estimate of the gaps which I have here indicated in the explanation of dreams as being due to somatic stimulation. These writers attempted to define more precisely the mental activities which lead to the production of such variegated dream-images from the somatic stimuli; in other words, they sought to regard dreaming once again as something essentially *mental* - as a psychical activity. Scherner did not merely depict the psychical characteristics unfolded in the production of dreams in terms charged with poetic feeling and glowing with life; he believed, too, that he had discovered the principle according to which the mind deals with the stimuli presented to it. On his view, the dream-work, when the imagination is set free from the shackles of daytime, seeks to give a *symbolic* representation of the nature of the organ from which the stimulus arises and of the nature of the stimulus itself. Thus he provides a kind of 'dream-book' to serve as a guide to the interpretation of dreams, which makes it possible to deduce from the dream-images inferences as to the somatic feelings, the state of the organs and the character of the stimuli concerned. 'Thus the image of a cat expresses a state of angry ill-temper, and the image of a smooth and lightly-coloured loaf of bread stands for physical nudity.' The human body as a whole is pictured by the dream-imagination as a house and the separate organs of the body by portions of a house. In 'dreams with a dental stimulus', an entrance-hall with a high, vaulted roof corresponds to the oral cavity and a staircase to the descent from the throat to the oesophagus. 'In dreams due to headaches, the top of the head is represented by the ceiling of a room covered with disgusting, toad-like spiders.' A variety of such symbols are employed by dreams to represent the same organ. 'Thus the breathing lung will be symbolically represented by a blazing furnace, with flames roaring with a sound like the passage of air; the heart will be represented by hollow boxes or baskets, the bladder by round, bag-shaped objects or, more generally, by hollow ones.' 'It is of special importance that at the end of a dream the organ concerned or its function is often openly revealed, and as a rule in relation to the dreamer's own body. Thus a dream with a dental stimulus usually ends by the dreamer picturing himself pulling a tooth out of his mouth.'

¹ [Footnote added 1919:] Cf. Landauer (1918) on behaviour during sleep. Anyone can observe persons asleep carrying out actions which obviously have a meaning. A man asleep is not reduced to complete idiocy; on the contrary, he is capable of logical and deliberate acts.

This theory of dream-interpretation cannot be said to have been very favourably received by other writers on the subject. Its main feature seems to be its extravagance; and there has even been hesitation in recognizing such justification as, in my opinion, it can lay claim to. As will have been seen, it involves a revival of dream-interpretation by means of *symbolism* - the same method that was employed in antiquity, except that the field from which interpretations are collected is restricted within the limits of the human body. Its lack of any technique of interpreting that can be grasped scientifically must greatly narrow the application of Scherner's theory. It seems to leave the door open to arbitrary interpretations, especially as in its case, too, the same stimulus can be represented in the dream content in a variety of different ways. Thus even Scherner's disciple, Volkelt, found himself unable to confirm the view that the body was represented by a house. Objections are also bound to arise from the fact that once again the mind is saddled with the dream-work as a useless and aimless function; for, according to the theory we are discussing, the mind is content with making phantasies about the stimulus with which it is occupied, without the remotest hint at anything in the nature of *disposing* of the stimulus.

There is one particular criticism, however, which is gravely damaging to Scherner's theory of the symbolization of somatic stimuli. These stimuli are present at all times and it is generally held that the mind is more accessible to them during sleep than when it is awake. It is difficult to understand, then, why the mind does not dream continuously all through the night, and, indeed, dream every night of all the organs. An attempt may be made to avoid this criticism by adding the further condition that in order to arouse dream-activity it is necessary for *special* excitations to proceed from the eyes, ears, teeth, intestines, etc. But the difficulty then arises of proving the objective nature of such increases of stimulus - which is only possible in a small number of cases. If dreams of flying are a symbolization of the rising and sinking of the lobes of the lungs, then, as Strümpell has already pointed out, either such dreams would have to be much more frequent than they are or it would be necessary to prove an increase in the activity of breathing in the course of them. There is a third possibility, which is the most probable of all, namely that special motives may be temporarily operative which direct the attention to visceral sensations that are uniformly present at all times. This possibility, however, carries us beyond the scope of Scherner's theory.

The value of the views put forward by Scherner and Volkelt lies in the fact that they draw attention to a number of characteristics of the content of dreams which call for explanation and seem to promise fresh discoveries. It is perfectly true that dreams contain symbolizations of bodily organs and functions, that water in a dream often points to a urinary stimulus, and that the male genitals can be represented by an upright stick or a pillar, and so on. In the case of dreams in which the field of vision is full of movement and bright colours, in contrast to the drabness of other dreams, it is scarcely possible not to interpret them as 'dreams with a visual stimulus'; nor can one dispute the part played by illusions in the case of dreams characterized by noise and a confusion of voices. Scherner reports a dream of two rows of pretty, fair-haired boys standing opposite each other on a bridge, and of their attacking each other and then going back to their original position, till at last the dreamer saw himself sitting down on a bridge and pulling a long tooth out of his jaw. Similarly Volkelt reports a dream in which two rows of drawers in a cupboard played a part and which once more ended with the dreamer pulling out a tooth. Dream-formations such as these, which are recorded in great numbers by the two authors, forbid our dismissing Scherner's theory as an idle invention without looking for its kernel of truth. The task, then, that faces us is to find an explanation of another kind for the supposed symbolization of what is alleged to be a dental stimulus.

Throughout the whole of this discussion of the theory of the somatic sources of dreams I have refrained from making use of the argument based upon my dream-analyses. If it can be proved, by a procedure which other writers have not employed upon their dream-material, that dreams possess a value of their own as psychical acts, that wishes are the motive for their construction and that experiences of the preceding day provide the immediate material for their content, then any other theory of dreams, which neglects so important a procedure of research and accordingly represents dreams as a useless and puzzling psychical reaction to somatic stimuli, stands condemned without there being any necessity for specific criticisms. Otherwise - and this seems highly improbable - there would have to be two quite different kinds of dreaming, one of which has come only under *my* observation and the other only under that of the earlier authorities. All that remains, therefore, is to find a place in my theory of dreams for the facts upon which the current theory of the somatic stimulation of dreams is based.

We have already taken the first step in this direction by advancing the thesis (see p. 666 f.) that the dream-work is under the necessity of combining into a unity all instigations to dreaming which are active simultaneously. We found that, when two or more experiences capable of creating an impression are left over from the previous day, the wishes derived from them are combined in a single dream, and similarly that the psychically significant impressions and the indifferent experiences from the previous day are brought together in the dream-material, provided always that it is possible to set up communicating ideas between them. Thus a dream appears to be a reaction to everything that is simultaneously present in the sleeping mind as currently active material. So far as we have hitherto analysed the material of dreams, we have seen it as a collection of psychical residues and memory-traces, to which (on account of the preference shown for recent and infantile material) we have been led to attribute a hitherto indefinable quality of being 'currently active'. We can foresee, then, without any great difficulty, what will happen if fresh material in the form of sensations is added during sleep to these currently active memories. It is once again owing to the fact of their being currently active that these sensory excitations are of importance for the dream; they are united with the other currently active psychical material to furnish what is used for the construction of the dream. To put it another way, stimuli arising during sleep are worked up into a wish-fulfilment the other constituents of which are the familiar psychical 'day's residues'. This combination *need* not occur; as I have already pointed out, there is more than one way of reacting to a somatic stimulus during sleep. When it *does* occur, it means that it has been possible to find ideational material to serve as the content of the dream of such a sort as to be able to represent both kinds of source of the dream - the somatic and the psychical.

The essential nature of the dream is not altered by the fact of somatic material being added to its psychical sources: a dream remains the fulfilment of a wish, no matter in what way the expression of that wish-fulfilment is determined by the currently active material.

I am prepared to leave room at this point for the operation of a number of special factors which can lend a varying importance to external stimuli in relation to dreams. As I picture it, a combination of individual factors, physiological and accidental, produced by the circumstances of the moment, is what determines how a person shall behave in particular cases of comparatively intense objective stimulation during sleep. The habitual or accidental depth of his sleep, taken in conjunction with the intensity of the stimulus, will make it possible in one case for him to suppress the stimulus so that his sleep is not interrupted and in another case will compel him to wake up or will encourage an attempt to overcome the stimulus by weaving it into a dream. In accordance with these various possible combinations, external objective stimuli will find expression in dreams with greater or less frequency in one person than in another. In my own case, since I am an excellent sleeper and obstinately refuse to allow anything to disturb my sleep, it very rarely happens that external causes of excitation find their way into my dreams; whereas psychical motives obviously cause me to dream very easily. In fact I have only noted a single dream in which an objective and painful source of stimulus is recognizable; and it will be most instructive to examine the effect which the external stimulus produced in this particular dream.

I was riding on a grey horse, timidly and awkwardly to begin with, as though I were only reclining upon it. I met one of my colleagues, P., who was sitting high on a horse, dressed in a tweed suit, and who drew my attention to something (probably to my bad seat). I now began to find myself sitting more and more firmly and comfortably on my highly intelligent horse, and noticed that I was feeling quite at home up there. My saddle was a kind of bolster, which completely filled the space between its neck and crupper. In this way I rode straight in between two vans. After riding some distance up the street, I turned round and tried to dismount, first in front of a small open chapel that stood in the street frontage. Then I actually did dismount in front of another chapel that stood near it. My hotel was in the same street; I might have let the horse go to it on its own, but I preferred to lead it there. It was as though I should have felt ashamed to arrive at it on horseback. A hotel 'boots' was standing in front of the hotel; he showed me a note of mine that had been found, and laughed at me over it. In the note was written, doubly underlined: 'No food' and then another remark (indistinct) such as 'No work', together with a vague idea that I was in a strange town in which I was doing no work.

It would not be supposed at first sight that this dream originated under the influence, or rather under the compulsion, of a painful stimulus. But for some days before I had been suffering from boils which made every movement a torture; and finally a boil the size of an apple had risen at the base of my scrotum, which caused me the most unbearable pain with every step I took. Feverish lassitude, loss of appetite and the hard work with which I nevertheless carried on - all these had combined with the pain to depress me. I was not properly capable of discharging my medical duties. There was, however, one activity for which, in view of the nature and situation of my complaint, I should certainly have been less fitted than for any other, and that was - riding. And this was precisely the activity in which the dream landed me: it was the most energetic denial of my illness that could possibly be imagined. I cannot in fact ride, nor have I, apart from this, had dreams of riding. I have only sat on a horse once in my life and that was without a saddle, and I did not enjoy it. But in this dream I was riding as though I had no boil on my perineum - or rather *because I wanted not to have one*. My saddle, to judge from its description, was the poultice which had made it possible for me to fall asleep. Under its assuaging influence I had probably been unaware of my pain during the first hours of sleep. The painful feelings had then announced themselves and sought to wake me; where upon the dream came and said soothingly: 'No! Go on sleeping! There's no need to wake up. You haven't got a boil; for you're riding on a horse, and it's quite certain that you couldn't ride if you had a boil in that particular place.' And the dream was successful. The pain was silenced, and I went on sleeping.

But the dream was not content with 'suggesting away' my boil by obstinately insisting upon an idea that was inconsistent with it and so behaving like the hallucinatory delusion of the mother who had lost her child or the merchant whose losses had robbed him of his fortune.¹ The details of the sensation which was being repudiated and of the picture which was employed in order to repress that sensation also served the dream as a means of connecting *other* material that was currently active in my mind with the situation in the dream and of giving that material representation. I was riding on a *grey* horse, whose colour corresponded precisely to the *pepper-and-salt* colour of the suit my colleague P. was wearing when I had last met him in the country. The cause of my boils had been ascribed to my eating *highly-spiced* food - an aetiology that was at least preferable to the *sugar* which might also occur to one in connection with boils. My friend P. liked to ride *the high horse* over me ever since he had taken over one of my women patients on whom I had pulled off some remarkable *feats*. (In the dream I began by riding tangentially - like the *feat* of a trick rider.) But in fact, like the horse in the anecdote of the Sunday horseman, this patient had taken me wherever she felt inclined. Thus the horse acquired the symbolic meaning of a woman patient. (It was *highly intelligent* in the dream.) '*I felt quite at home up there*' referred to the position I had occupied in this patient's house before I was replaced by P. Not long before, one of my few patrons among the leading physicians in this city had remarked to me in connection with this same house: 'You struck me as being firmly in the saddle there.' It was a remarkable *feat*, too, to be able to carry on my psychotherapeutic work for eight or ten hours a day while I was having so much pain. But I knew that I could not go on long with my peculiarly difficult work unless I was in completely sound physical health; and my dream was full of gloomy allusions to the situation in which I should then find myself. (The *note* which neurasthenics bring with them to show the doctor; *no work, no food*.) In the course of further interpretation I saw that the dream-work had succeeded in finding a path from the wishful situation of riding to some scenes of quarrelling from my very early childhood which must have occurred between me and a nephew of mine, a year my senior, who was at present living in England. Furthermore, the dream had derived some of its elements from my travels in Italy: the street in the dream was composed of impressions of Verona and Siena. A still deeper interpretation led to sexual dream-thoughts, and I recalled the meaning which references to Italy seem to have had in the dreams of a woman patient who had never visited that lovely country: '*gen Italien* [to Italy]' - '*Genitalien* [genitals]'; and this was connected, too, with the house in which I had preceded my friend P. as physician, as well as with the situation of my boil.

¹ Cf. the passage in Griesinger and my remarks in my second paper on the neuro-psychoses of defence (Freud, 1896b).

In another dream I similarly succeeded in warding off a threatened interruption of my sleep which came this time from a sensory stimulus. In this case it was only by chance, however, that I was able to discover the link between the dream and its accidental stimulus and thus to understand the dream. One morning at the height of summer, while I was staying at a mountain resort in the Tyrol, I woke up knowing I had had a dream that *the Pope was dead*. I failed to interpret this dream - a non-visual one - and only remembered as part of its basis that I had read in a newspaper a short time before that his Holiness was suffering from a slight indisposition. In the course of the morning, however, my wife asked me if I had heard the frightful noise made by the pealing of bells that morning. I had been quite unaware of them, but I now understood my dream. It had been a reaction on the part of my need for sleep to the noise with which the pious Tyrolese had been trying to wake me. I had taken my revenge on them by drawing the inference which formed the content of the dream, and I had then continued my sleep without paying any more attention to the noise.

The dreams quoted in earlier chapters included several which might serve as instances of the working-over of such so-called nervous stimuli. My dream of drinking water in great gulps is an example. The somatic stimulus was apparently its only source, and the wish derived from the sensation (the thirst, that is) was apparently its only motive. The case is similar with other simple dreams in which a somatic stimulus seems able by itself to construct a wish. The dream of the woman patient who threw off the cooling apparatus from her cheek during the night presents an unusual method of reacting to a painful stimulus with a wish-fulfilment: it appears as though the patient succeeded temporarily in making herself analgesic, while ascribing her pains to someone else.

My dream of the three Fates was clearly a hunger dream. But it succeeded in shifting the craving for nourishment back to a child's longing for his mother's breast, and it made use of an innocent desire as a screen for a more serious one which could not be so openly displayed. My dream about Count Thun showed how an accidental physical need can be linked up with the most intense (but at the same time the most intensely suppressed) mental impulses. And a case such as that related by Garnier (1872, 1, 476) of how the First Consul wove the noise of an exploding bomb into a battle dream before he woke up from it reveals with quite special clarity the nature of the sole motive that leads mental activity to concern itself with sensations during sleep. A young barrister, fresh from his first important bankruptcy proceedings, who dropped asleep one afternoon, behaved in just the same way as the great Napoleon. He had a dream of a certain G. Reich of *Husyatin* whom he had come across during a bankruptcy case; the name 'Husyatin' kept on forcing itself on his notice, till he woke up and found that his wife (who was suffering from a bronchial catarrh) was having a violent fit of coughing [in German '*husten*'].

Let us compare this dream of the first Napoleon (who, incidentally, was an extremely sound sleeper) with that of the sleepy student who was roused by his landlady and told that it was time to go to the hospital, and who proceeded to dream that he was in bed at the hospital and then slept on, under the pretext that as he was already in the hospital there was no need for him to get up and go there. This latter dream was clearly a dream of convenience. The dreamer admitted his motive for dreaming without any disguise; but at the same time he gave away one of the secrets of dreaming in general. All dreams are in a sense dreams of convenience: they serve the purpose of prolonging sleep instead of waking up. *Dreams are the GUARDIANS of sleep and not its disturbers.* We shall have occasion elsewhere to justify this view of them in relation to awakening factors of a *psychical* kind; but we are already in a position to show that it is applicable to the part played by objective external stimuli. Either the mind pays no attention at all to occasions for sensation during sleep - if it is able to do this despite the intensity of the stimuli and the significance which it knows attaches to them; or it makes use of a dream in order to deny the stimuli; or, thirdly, if it is obliged to recognize them, it seeks for an interpretation of them which will make the currently active sensation into a component part of a situation which is wished for and which is consistent with sleeping. The currently active sensation is woven into a dream *in order to rob it of reality.* Napoleon could sleep on - with a conviction that what was trying to disturb him was only a dream-memory of the thunder of the guns at Arcole.¹

¹ The two sources from which I know this dream do not agree in their account of it.

Thus the wish to sleep (which the conscious ego is concentrated upon, and which, together with the dream-censorship and the 'secondary revision' which I shall mention later, constitute the conscious ego's share in dreaming) must in every case be reckoned as one of the motives for the formation of dreams, and every successful dream is a fulfilment of that wish. We shall discuss elsewhere the relations subsisting between this universal, invariably present and unchanging wish to sleep and the other wishes, of which now one and now another is fulfilled by the content of the dream. But we have found in the wish to sleep the factor that is able to fill the gap in the theory of Strümpell and Wundt and to explain the perverse and capricious manner in which external stimuli are interpreted. The correct interpretation, which the sleeping mind is perfectly capable of making, would involve an active interest and would require that sleep should be brought to an end; for that reason, of all the possible interpretations, only those are admitted which are consistent with the absolute censorship exercised by the wish to sleep. 'It is the nightingale and not the lark.' For if it were the lark it would mean the end of the lovers' night. Among the interpretations of the stimulus which are accordingly admissible, that one is then selected which can provide the best link with the wishful impulses lurking in the mind. Thus everything is unambiguously determined and nothing is left to arbitrary decision. The misinterpretation is not an illusion but, as one might say, an evasion. Here once again, however, just as when, in obedience to the dream-censorship, a substitution is effected by displacement, we have to admit that we are faced by an act which deviates from normal psychical processes.

When external nervous stimuli and internal somatic stimuli are intense enough to force psychical attention to themselves, then - provided that their outcome is dreaming and not waking up - they serve as a fixed point for the formation of a dream, a nucleus in its material; a wish-fulfilment is then looked for that shall correspond to this nucleus, just as (see above) intermediate ideas are looked for between two psychical dream stimuli. To that extent it is true that in a number of dreams the content of the dream is dictated by the somatic element. In this extreme instance it may even happen that a wish which is not actually a currently active one is called up for the sake of constructing a dream. A dream, however, has no alternative but to represent a wish in the situation of having been fulfilled; it is, as it were, faced with the problem of looking for a wish which can be represented as fulfilled by the currently active sensation. If this immediate material is of a painful or distressing kind, that does not necessarily mean that it cannot be used for the construction of a dream. The mind has wishes at its disposal whose fulfilment produces unpleasure. This seems self-contradictory; but it becomes intelligible when we take into account the presence of two psychical agencies and a censorship between them.

As we have seen, there are 'repressed' wishes in the mind, which belong to the first system and whose fulfilment is opposed by the second system. In saying that there are such wishes I am not making a historical statement to the effect that they once existed and were later abolished. The theory of repression, which is essential to the study of the psychoneuroses, asserts that these repressed wishes *still* exist - though there is a simultaneous inhibition which holds them down. Linguistic usage hits the mark in speaking of the 'suppression' of these impulses. The psychical arrangements that make it possible for such impulses to force their way to realization remain in being and in working order. Should it happen, however, that a suppressed wish of this kind is carried into effect, and that its inhibition by the second system (the system that is admissible to consciousness) is defeated, this defeat finds expression as unpleasure. In conclusion: if sensations of an unpleasurable nature arising from somatic sources occur during sleep, the dream-work makes use of that event in order to represent - subject to the continuance of the censorship to a greater or less degree - the fulfilment of some wish which is normally suppressed.

This state of affairs is what makes possible one group of anxiety-dreams - dream-structures unpropitious from the point of view of the wish-theory. A second group of them reveal a different mechanism; for anxiety in dreams may be psychoneurotic anxiety: it may originate from psychosexual excitations - in which case the anxiety corresponds to repressed libido. Where this is so, the anxiety, like the whole anxiety-dream, has the significance of a neurotic symptom, and we come near the limit at which the wish-fulfilling purpose of dreams breaks down. But there are some anxiety dreams in which the feeling of anxiety is determined somatically - where, for instance, there happens to be difficulty in breathing owing to disease of the lungs or heart - and in such cases the anxiety is exploited in order to assist the fulfilment in the form of dreams of energetically suppressed wishes which, if they had been dreamt about for *psychical* reasons, would have led to a similar release of anxiety. But there is no difficulty in reconciling these two apparently different groups. In both groups of dreams two psychical factors are involved: an inclination towards an affect and an ideational content; and these are intimately related to each other. If one of them is currently active, it calls up the other even in a dream; in the one case the somatically determined anxiety calls up the suppressed ideational content, and in the other the ideational content with its accompanying sexual excitation, having been set free from repression, calls up a release of anxiety. We can put it that in the first case a somatically determined affect is given a psychical interpretation; while in the other case, though the whole is psychically determined, the content which had been suppressed is easily replaced by a somatic interpretation appropriate to anxiety. The difficulties which all this offers to our understanding have little to do with dreams: they arise from the fact that we are here touching on the problem of the generation of anxiety and on the problem of repression.

There can be no doubt that physical coenaesthesia is among the internal somatic stimuli which can dictate the content of dreams. It can do so, not in the sense that it can provide the dream's content, but in the sense that it can force upon the dream-thoughts a choice of the material to be represented in the content by putting forward one part of the material as being appropriate to its own character and by holding back another part. Apart from this, the coenaesthetic feelings left over from the preceding day link themselves up, no doubt, with the psychical residues which have such an important influence on dreams. This general mood may persist unchanged in the dream or it may be mastered, and thus, if it is unpleasurable, may be changed into its opposite.

Thus, in my opinion, somatic sources of stimulation during sleep (that is to say, sensations during sleep), unless they are of unusual intensity, play a similar part in the formation of dreams to that played by recent but indifferent impressions left over from the previous day. I believe, that is, that they are brought in to help in the formation of a dream if they fit in appropriately with the ideational content derived from the dream's psychical sources, but otherwise not. They are treated like some cheap material always ready to hand, which is employed whenever it is needed, in contrast to a precious material which itself prescribes the way in which it shall be employed. If, to take a simile, a patron of the arts brings an artist some rare stone, such as a piece of onyx, and asks him to create a work of art from it, then the size of the stone, its colour and markings, help to decide what head or what scene shall be represented in it. Whereas in the case of a uniform and plentiful material such as marble or sandstone, the artist merely follows some idea that is present in his own mind. It is only in this way, so it seems to me, that we can explain the fact that dream-content provided by somatic stimuli of no unusual intensity fails to appear in every dream or every night.¹

¹ [*Footnote added 1914:*] Rank has shown in a number of papers that certain arousal dreams produced by organic stimuli (dreams with a urinary stimulus and dreams of emission or orgasm) are especially suited to demonstrate the struggle between the need to sleep and the claims of organic needs, as well as the influence of the latter upon the content of dreams.

I can perhaps best illustrate my meaning by an example, which, moreover, will bring us back to dream-interpretation.

One day I had been trying to discover what might be the meaning of the feelings of being inhibited, of being glued to the spot, of not being able to get something done, and so on, which occur so often in dreams and are so closely akin to feelings of anxiety. That night I had the following dream:

I was very incompletely dressed and was going upstairs from a flat on the ground floor to a higher storey. I was going up three steps at a time and was delighted at my agility. Suddenly I saw a maid-servant coming down the stairs - coming towards me, that is. I felt ashamed and tried to hurry, and at this point the feeling of being inhibited set in: I was glued to the steps and unable to budge from the spot.

ANALYSIS. -The situation in the dream is taken from everyday reality. I occupy two flats in a house in Vienna, which are connected only by the public staircase. My consulting-room and study are on the upper ground floor and my living rooms are one storey higher. When, late in the evening, I have finished my work down below, I go up the stairs to my bedroom. On the evening before I had the dream, I had in fact made this short journey in rather disordered dress - that is to say, I had taken off my collar and tie and cuffs. In the dream this had been turned into a higher degree of undress, but, as usual, an indeterminate one. I usually go upstairs two or three steps at a time; and this was recognized in the dream itself as a wish-fulfilment: the ease with which I achieved it reassured me as to the functioning of my heart. Further, this method of going upstairs was an effective contrast to the inhibition in the second half of the dream. It showed me - what needed no proving - that dreams find no difficulty in representing motor acts carried out to perfection. (One need only recall dreams of flying.)

The staircase up which I was going, however, was not the one in my house. At first I failed to recognize it and it was only the identity of the person who met me that made it clear to me what locality was intended. This person was the maid-servant of the old lady whom I was visiting twice a day in order to give her injections; and the staircase, too, was just like the one in her house which I had to go up twice a day.

Now how did this staircase and this female figure come to be in my dream? The feeling of shame at not being completely dressed is no doubt of a sexual nature; but the maid-servant whom I dreamt about was older than I am, surly and far from attractive. The only answer to the problem that occurred to me was this. When I paid my morning visits to this house I used as a rule to be seized with a desire to clear my throat as I went up the stairs and the product of my expectoration would fall on the staircase. For on neither of these floors was there a spittoon; and the view I took was that the cleanliness of the stairs should not be maintained at my expense but should be made possible by the provision of a spittoon. The concierge, an equally elderly and surly woman (but of cleanly instincts, as I was prepared to admit), looked at the matter in a different light. She would lie in wait for me to see whether I should again make free of the stairs, and, if she found that I did, I used to hear her grumbling audibly; and for several days afterwards she would omit the usual greeting when we met. The day before I had the dream the concierge's party had received a reinforcement in the shape of the maid-servant. I had, as usual, concluded my hurried visit to the patient, when the servant stopped me in the hall and remarked: 'You might have wiped your boots, doctor, before you came into the room to-day. You've made the red carpet all dirty again with your feet.' This was the only claim the staircase and the maid-servant had to appearing in my dream.

There was an internal connection between my running up the stairs and my spitting on the stairs. Pharyngitis as well as heart trouble are both regarded as punishments for the vice of smoking. And on account of that habit my reputation for tidiness was not of the highest with the authorities in my own house any more than in the other; so that the two were fused into one in the dream.

I must postpone my further interpretation of this dream till I can explain the origin of the typical dream of being incompletely dressed. I will only point out as a provisional conclusion to be drawn from the present dream that a sensation of inhibited movement in dreams is produced whenever the particular context requires it. The cause of this part of the dream's content cannot have been that some special modification in my powers of movement had occurred during my sleep, since only a moment earlier I had seen myself (almost as though to confirm this fact) running nimbly up the stairs.

(D)

TYPICAL DREAMS

We are not in general in a position to interpret another person's dream unless he is prepared to communicate to us the unconscious thoughts that lie behind its content. The practical applicability of our method of interpreting dreams is in consequence severely restricted.¹ We have seen that, as a general rule, each person is at liberty to construct his dream-world according to his individual peculiarities and so to make it unintelligible to other people. It now appears, however, that, in complete contrast to this, there are a certain number of dreams which almost everyone has dreamt alike and which we are accustomed to assume must have the same meaning for everyone. A special interest attaches, moreover, to these typical dreams because they presumably arise from the same sources in every case and thus seem particularly well qualified to throw light on the sources of dreams.

It is therefore with quite particular anticipations that we shall attempt to apply our technique of dream-interpretation to these typical dreams; and it is with great reluctance that we shall have to confess that our art disappoints our expectations precisely in relation to this material. If we attempt to interpret a typical dream, the dreamer fails as a rule to produce the associations which would in other cases have led us to understand it, or else his associations become obscure and insufficient so that we cannot solve our problem with their help. We shall learn in a later portion of this work why this is so and how we can make up for this defect in our technique. My readers will also discover why it is that at the present point I am able to deal only with a few members of the group of typical dreams and must postpone my consideration of the rest until this later point in my discussion.

¹ [*Footnote added 1925:*] This assertion that our method of interpreting dreams cannot be applied unless we have access to the dreamer's associative material requires supplementing: our interpretative activity is in one instance independent of these associations - if, namely, the dreamer has employed symbolic elements in the content of the dream. In such case we make use of what is, strictly speaking, a second and auxiliary method of dream-interpretation. (See below.)

(α) EMBARRASING DREAMS OF BEING NAKED

Dreams of being naked or insufficiently dressed in the presence of strangers sometimes occur with the additional feature of there being a complete absence of any such feeling as shame on the dreamer's part. We are only concerned here, however, with those dreams of being naked in which one *does* feel shame and embarrassment and tries to escape or hide, and is then overcome by a strange inhibition which prevents one from moving and makes one feel incapable of altering one's distressing situation. It is only with this accompaniment that the dream is typical; without it, the gist of its subject-matter may be included in every variety of context or may be ornamented with individual trimmings. Its essence lies in a distressing feeling in the nature of shame and in the fact that one wishes to hide one's nakedness, as a rule by locomotion, but finds one is unable to do so. I believe the great majority of my readers will have found themselves in this situation in dreams.

The nature of the undress involved is customarily far from clear. The dreamer may say 'I was in my chemise', but this is rarely a distinct picture. The kind of undress is usually so vague that the description is expressed as an alternative: 'I was in my chemise or petticoat.' As a rule the defect in the dreamer's toilet is not so grave as to appear to justify the shame to which it gives rise. In the case of a man who has worn the Emperor's uniform, nakedness is often replaced by some breach of the dress regulations: 'I was walking in the street without my sabre and saw some officers coming up', or 'I was without my necktie', or 'I was wearing civilian check trousers', and so on.

The people in whose presence one feels ashamed are almost always strangers, with their features left indeterminate. In the typical dream it never happens that the clothing which causes one so much embarrassment is objected to or so much as noticed by the onlookers. On the contrary, they adopt indifferent or (as I observed in one particularly clear dream) solemn and stiff expressions of face. This is a suggestive point.

The embarrassment of the dreamer and the indifference of the onlookers offer us, when taken together, a contradiction of the kind that is so common in dreams. It would after all be more in keeping with the dreamer's feelings if strangers looked at him in astonishment and derision or with indignation. But this objectionable feature of the situation has, I believe, been got rid of by wish-fulfilment, whereas some force has led to the retention of the other features; and the two portions of the dream are consequently out of harmony with each other. We possess an interesting piece of evidence that the dream in the form in which it appears - partly distorted by wish-fulfilment - has not been rightly understood. For it has become the basis of a fairy tale which is familiar to us all in Hans Andersen's version, *The Emperor's New Clothes*, and which has quite recently been put into verse by Ludwig Fulda in his *Der Talisman*. Hans Andersen's fairy tale tells us how two impostors weave the Emperor a costly garment which, they say, will be visible only to persons of virtue and loyalty. The Emperor walks out in this invisible garment, and all the spectators, intimidated by the fabric's power to act as a touchstone, pretend not to notice the Emperor's nakedness.

This is just the situation in our dream. It is hardly rash to assume that the unintelligibility of the dream's content, as it exists in the memory has led to its being recast in a form designed to make sense of the situation. That situation, however, is in the process deprived of its original meaning and put to extraneous uses. But, as we shall see later, it is a common thing for the conscious thought-activity of a second psychical system to misunderstand the content of a dream in this way, and this misunderstanding must be regarded as one of the factors in determining the final form assumed by dreams. Moreover we shall learn that similar misunderstandings (taking place, once again, within one and the same psychical personality) play a major part in the construction of obsessions and phobias.

In the case of our dream we are in a position to indicate the material upon which the misinterpretation is based. The impostor is the dream and the Emperor is the dreamer himself; the moralizing purpose of the dream reveals an obscure knowledge of the fact that the latent dream-content is concerned with forbidden wishes that have fallen victim to repression. For the context in which dreams of this sort appear during my analyses of neurotics leaves no doubt that they are based upon memories from earliest childhood. It is only in our childhood that we are seen in inadequate clothing both by members of our family and by strangers - nurses, maid-servants, and visitors; and it is only then that we feel no shame at our nakedness.¹ We can observe how undressing has an almost intoxicating effect on many children even in their later years, instead of making them feel ashamed. They laugh and jump about and slap themselves, while their mother, or whoever else may be there, reproves them and says: 'Ugh! Shocking! You mustn't ever do that!' Children frequently manifest a desire to exhibit. One can scarcely pass through a country village in our part of the world without meeting some child of two or three who lifts up his little shirt in front of one - in one's honour, perhaps. One of my patients has a conscious memory of a scene in his eighth year, when at bed-time he wanted to dance into the next room where his little sister slept, dressed in his night-shirt, but was prevented by his nurse. In the early history of neurotics an important part is played by exposure to children of the opposite sex; in paranoia delusions of being observed while dressing and undressing are to be traced back to experiences of this kind; while among persons who have remained at the stage of perversion there is one class in which this infantile impulse has reached the pitch of a symptom - the class of 'exhibitionists'.

¹ A child plays a part in the fairy tale as well; for it was a small child who suddenly exclaimed: 'But he has nothing on!'

When we look back at this unashamed period of childhood it seems to us a Paradise; and Paradise itself is no more than a group phantasy of the childhood of the individual. That is why mankind were naked in Paradise and were without shame in one another's presence; till a moment arrived when shame and anxiety awoke, expulsion followed, and sexual life and the tasks of cultural activity began. But we can regain this Paradise every night in our dreams. I have already expressed a suspicion that impressions of earliest childhood (that is, from the prehistoric epoch until about the end of the third year of life) strive to achieve reproduction, from their very nature and irrespectively perhaps of their actual content, and that their repetition constitutes the fulfilment of a wish. Thus dreams of being naked are dreams of exhibiting.¹

The core of a dream of exhibiting lies in the figure of the dreamer himself (not as he was as a child but as he appears at the present time) and his inadequate clothing (which emerges indistinctly, whether owing to superimposed layers of innumerable later memories of being in undress or as a result of the censorship). Added to these are the figures of the people in whose presence the dreamer feels ashamed. I know of no instance in which the actual spectators of the infantile scene of exhibiting have appeared in the dream; a dream is scarcely ever a simple memory. Curiously enough, the people upon whom our sexual interest was directed in childhood are omitted in all the reproductions which occur in dreams, in hysteria and in obsessional neurosis. It is only in paranoia that these spectators reappear and, though they remain invisible, their presence is inferred with fanatical conviction. What takes their place in dreams - 'a lot of strangers' who take no notice of the spectacle that is offered - is nothing more nor less than the wishful contrary of the single familiar individual before whom the dreamer exposed himself. Incidentally, 'a lot of strangers' frequently appear in dreams in many other connections, and they always stand as the wishful contrary of 'secrecy'. It is to be noticed that even in paranoia, where the original state of things is restored, this reversal into a contrary is observed. The subject feels that he is no longer alone, he has no doubt that he is being observed, but the observers are 'a lot of strangers' whose identity is left curiously vague.

¹ [Footnote added 1911:] Ferenczi has recorded a number of interesting dreams of being naked dreamt by *women*. There was no difficulty in tracing these back to the infantile desire to exhibit; but they differed in some respects from the 'typical' dreams of being naked which I have discussed in the text.

In addition to this, repression plays a part in dreams of exhibiting; for the distress felt in such dreams is a reaction on the part of the second system against the content of the scene of exhibiting having found expression in spite of the ban upon it. If the distress was to be avoided, the scene should never have been revived.

We shall return later to the feeling of being inhibited. It serves admirably in dreams to represent a conflict in the will or a negative. The unconscious purpose requires the exhibiting to proceed; the censorship demands that it shall be stopped.

There can be no doubt that the connections between our typical dreams and fairy tales and the material of other kinds of creative writing are neither few nor accidental. It sometimes happens that the sharp eye of a creative writer has an analytic realization of the process of transformation of which he is habitually no more than the tool. If so, he may follow the process in a reverse direction and so trace back the imaginative writing to a dream. One of my friends has drawn my attention to the following passage in Gottfried Keller's *Der grüne Heinrich*: 'I hope, my dear Lee, that you may never learn from your own personal experience the peculiar and *piquant* truth of the plight of Odysseus when he appeared, naked and covered with mud, before the eyes of Nausicaä and her maidens! Shall I tell you how that can happen? Let us look into our example. If you are wandering about in a foreign land, far from your home and from all that you hold dear, if you have seen and heard many things, have known sorrow and care, and are wretched and forlorn, then without fail you will dream one night that you are coming near to your home; you will see it gleaming and shining in the fairest colours, and the sweetest, dearest and most beloved forms will move towards you. Then suddenly you will become aware that you are in rags, naked and dusty. You will be seized with a nameless shame and dread, you will seek to find covering and to hide yourself, and you will awake bathed in sweat. This, so long as men breathe, is the dream of the unhappy wanderer; and Homer has evoked the picture of his plight from the deepest and eternal nature of man.'

The deepest and eternal nature of man, upon whose evocation in his hearers the poet is accustomed to rely, lies in those impulses of the mind which have their roots in a childhood that has since become prehistoric. Suppressed and forbidden wishes from childhood break through in the dream behind the exile's unobjectionable wishes which are capable of entering consciousness; and that is why the dream which finds concrete expression in the legend of Nausicaä ends as a rule as an anxiety-dream.

My own dream (recorded on p. 717) of running upstairs and of soon afterwards finding myself glued to the steps was equally a dream of exhibiting, since it bears the essential marks of being one. It should be possible, therefore, to trace it back to experiences during my childhood, and if these could be discovered they should enable us to judge how far the maid-servant's behaviour to me - her accusing me of dirtying the carpet - helped to give her her place in my dream. I can, as it happens, provide the necessary particulars. In a psycho-analysis one learns to interpret propinquity in time as representing connection in subject-matter. Two thoughts which occur in immediate sequence without any apparent connection are in fact part of a single unity which has to be discovered; in just the same way, if I write an 'a' and a 'b' in succession, they have to be pronounced as a single syllable 'ab'. The same is true of dreams. The staircase dream to which I have referred was one of a series of dreams; and I understood the interpretation of the other members of the series. Since this particular dream was surrounded by the others it must have dealt with the same subject. Now these other dreams were based on a recollection of a nurse in whose charge I had been from some date during my earliest infancy till I was two and a half. I even retain an obscure conscious memory of her. According to what I was told not long ago by my mother, she was old and ugly, but very sharp and efficient. From what I can infer from my own dreams her treatment of me was not always excessive in its amiability and her words could be harsh if I failed to reach the required standard of cleanliness. And thus the maid servant, since she had undertaken the job of carrying on this educational work, acquired the right to be treated in my dream as a reincarnation of the prehistoric old nurse. It is reasonable to suppose that the child loved the old woman who taught him these lessons, in spite of her rough treatment of him.¹

¹ Here is an 'over-interpretation' of the same dream. Since '*spuken* [haunting]' is an activity of *spirits*, '*spucken* [spitting] on the stairs' might be loosely rendered as '*esprit d'escalier*'. This last phrase is equivalent to lack of ready repartee ['*Schlagfertigkeit*', literally 'readiness to strike'] - a failing to which I must in fact plead guilty. Was my nurse, I wonder, equally wanting in that quality?

(β) DREAMS OF THE DEATH OF PERSONS OF WHOM THE DREAMER IS FOND

Another group of dreams which may be described as typical are those containing the death of some loved relative - for instance, of a parent, of a brother or sister, or of a child. Two classes of such dreams must at once be distinguished: those in which the dreamer is unaffected by grief, so that on awakening he is astonished at his lack of feeling, and those in which the dreamer feels deeply pained by the death and may even weep bitterly in his sleep.

We need not consider the dreams of the first of these classes, for they have no claim to be regarded as 'typical'. If we analyse them, we find that they have some meaning other than their apparent one, and that they are intended to conceal some other wish. Such was the dream of the aunt who saw her sister's only son lying in his coffin. (See p. 647.) It did not mean that she wished her little nephew dead; as we have seen, it merely concealed a wish to see a particular person of whom she was fond and whom she had not met for a long time - a person whom she had once before met after a similarly long interval beside the coffin of another nephew. This wish, which was the true content of the dream, gave no occasion for grief, and no grief, therefore, was felt in the dream. It will be noticed that the affect felt in the dream belongs to its latent and not to its manifest content, and that the dream's *affective* content has remained untouched by the distortion which has overtaken its *ideational* content.

Very different are the dreams of the other class - those in which the dreamer imagines the death of a loved relative and is at the same time painfully affected. The meaning of such dreams, as their content indicates, is a wish that the person in question may die. And since I must expect that the feelings of all of my readers and any others who have experienced similar dreams will rebel against my assertion, I must try to base my evidence for it on the broadest possible foundation.

I have already discussed a dream which taught us that the wishes which are represented in dreams as fulfilled are not always present-day wishes. They may also be wishes of the past which have been abandoned, overlaid and repressed, and to which we have to attribute some sort of continued existence only because of their re-emergence in a dream. They are not dead in our sense of the word but only like the shades in the *Odyssey*, which awoke to some sort of life as soon as they had tasted blood. In the dream of the dead child in the 'case' (p. 154) what was involved was a wish which had been an immediate one fifteen years earlier and was frankly admitted as having existed at that time. I may add - and this may not be without its bearing upon the theory of dreams - that even behind this wish there lay a memory from the dreamer's earliest childhood. When she was a small child - the exact date could not be fixed with certainty - she had heard that her mother had fallen into a deep depression during the pregnancy of which she had been the fruit and had passionately wished that the child she was bearing might die. When the dreamer herself was grown-up and pregnant, she merely followed her mother's example.

If anyone dreams, with every sign of pain, that his father or mother or brother or sister has died, I should never use the dream as evidence that he wishes for that person's death of *at the present time*. The theory of dreams does not require as much as that; it is satisfied with the inference that this death has been wished for at some time or other during the dreamer's childhood. I fear, however, that this reservation will not appease the objectors; they will deny the possibility of their *ever* having had such a thought with just as much energy as they insist that they harbour no such wishes now. I must therefore reconstruct a portion of the vanished mental life of children on the basis of the evidence of the present.¹

¹ [Footnote added 1909:] Cf. my 'Analysis of a Phobia in a Five-Year Old Boy' (1909*b*) and my paper 'On the Sexual Theories of Children' (1908*c*).

Let us first consider the relation of children to their brothers and sisters. I do not know why we presuppose that that relation must be a loving one; for instances of hostility between adult brothers and sisters force themselves upon everyone's experience and we can often establish the fact that the disunity originated in childhood or has always existed. But it is further true that a great many adults, who are on affectionate terms with their brothers and sisters and are ready to stand by them to-day, passed their childhood on almost unbroken terms of enmity with them. The elder child ill-treats the younger, maligns him and robs him of his toys; while the younger is consumed with impotent rage against the elder, envies and fears him, or meets his oppressor with the first stirrings of a love of liberty and a sense of justice. Their parents complain that the children do not get on with one another, but cannot discover why. It is easy to see that the character of even a good child is not what we should wish to find it in an adult. Children are completely egoistic; they feel their needs intensely and strive ruthlessly to satisfy them - especially as against the rivals, other children, and first and foremost as against their brothers and sisters. But we do not on that account call a child 'bad', we call him 'naughty'; he is no more answerable for his evil deeds in our judgement than in the eyes of the law. And it is right that this should be so; for we may expect that, before the end of the period which we count as childhood, altruistic impulses and morality will awaken in the little egoist and (to use Meynert's terms) a secondary ego will overlay and inhibit the primary one. It is true, no doubt, that morality does not set in simultaneously all along the line and that the length of non-moral childhood varies in different individuals. If this morality fails to develop, we like to talk of 'degeneracy', though what in fact faces us is an inhibition in development. After the primary character has already been overlaid by later development, it can still be laid bare again, at all events in part, in cases of hysterical illness. There is a really striking resemblance between what is known as the hysterical character and that of a naughty child. Obsessional neurosis, on the contrary, corresponds to a super-morality imposed as a reinforcing weight upon fresh stirrings of the primary character.

Many people, therefore, who love their brothers and sisters and would feel bereaved if they were to die, harbour evil wishes against them in their unconscious, dating from earlier times; and these are capable of being realized in dreams.

It is of quite particular interest, however, to observe the behaviour of small children up to the age of two or three or a little older towards their younger brothers and sisters. Here, for instance, was a child who had so far been the only one; and now he was told that the stork had brought a new baby. He looked the new arrival up and down and then declared decisively: 'The stork can take him away again!'¹ I am quite seriously of the opinion that a child can form a just estimate of the set-back he has to expect at the hands of the little stranger. A lady of my acquaintance, who is on very good terms to-day with a sister four years her junior, tells me that she greeted the news of her first arrival with this qualification: 'But all the same I shan't give her my red cap!' Even if a child only comes to realize the situation later on, his hostility will date from that moment. I know of a case in which a little girl of less than three tried to strangle an infant in its cradle because she felt that its continued presence boded her no good. Children at that time of life are capable of jealousy of any degree of intensity and obviousness. Again, if it should happen that the baby sister does in fact disappear after a short while, the elder child will find the whole affection of the household once more concentrated upon himself. If after that the stork should bring yet another baby, it seems only logical that the little favourite should nourish a wish that his new competitor may meet with the same fate as the earlier one, so that he himself may be as happy as he was originally and during the interval.² Normally, of course, this attitude of a child towards a younger brother or sister is a simple function of the difference between their ages. Where the gap in time is sufficiently long, an elder girl will already begin to feel the stirring of her maternal instincts towards the helpless new born baby.

¹ [Footnote added 1909:] The three-and-a-half-year-old Hans (whose phobia was the subject of the analysis mentioned in the preceding footnote) exclaimed shortly after the birth of a sister, while he was suffering from a feverish sore throat: 'I don't *want* a baby sister!' During his neurosis eighteen months later he frankly confessed to a wish that his mother might drop the baby into the bath so that the would die. At the same time, Hans was a good-natured and affectionate child, who soon grew fond of this same sister and particularly enjoyed taking her under his wing.

² [Footnote added 1914:] Deaths that are experienced in this way in childhood may quickly be forgotten in the family; but psycho-analytic research shows that they have a very important influence on subsequent neuroses.

Hostile feelings towards brothers and sisters must be far more frequent in childhood than the unseeing eye of the adult observer can perceive.¹

In the case of my own children, who followed each other in rapid succession, I neglected the opportunity of carrying out observations of this kind; but I am now making up for this neglect by observing a small nephew, whose autocratic rule was upset, after lasting for fifteen months, by the appearance of a female rival. I am told, it is true, that the young man behaves in the most chivalrous manner to his little sister, that he kisses her hand and strokes her; but I have been able to convince myself that even before the end of his second year he made use of his powers of speech for the purpose of criticizing someone whom he could not fail to regard as superfluous. Whenever the conversation touched upon her he used to intervene in it and exclaim petulantly: 'Too 'ickle! too 'ickle!' During the last few months the baby's growth has made enough progress to place her beyond this particular ground for contempt, and the little boy has found a different basis for his assertion that she does not deserve so much attention: at every suitable opportunity he draws attention to the fact that she has no teeth.² We all of us recollect how the eldest girl of another of my sisters, who was then a child of six, spent half an hour in insisting upon each of her aunts in succession agreeing with her: 'Lucie can't understand that yet, can she?' she kept asking. Lucie was her rival - two and a half years her junior.

¹ [*Footnote added 1914:*] Since this was written, a large number of observations have been made and recorded in the literature of psycho-analysis upon the originally hostile attitude of children towards their brothers and sisters and one of their parents. The author and poet Spitteler has given us a particularly genuine and naïve account of this childish attitude, derived from his own childhood: 'Moreover there was a second Adolf there: a little creature who they alleged was my brother, though I could not see what use he was and still less why they made as much fuss of him as of me myself. I was sufficient so far as I was concerned; why should I want a brother? And he was not merely useless, he was positively in the way. When I pestered my grandmother, he wanted to pester her too. When I was taken out in the perambulator, he sat opposite to me and took up half the space, so that we were bound to kick each other with our feet.'

² [*Footnote added 1909:*] Little Hans, when he was three and a half, gave vent to a crushing criticism of his sister in the same words. It was because of her lack of teeth, he supposed, that she was unable to talk.

In none of my women patients, to take an example, have I failed to come upon this dream of the death of a brother or sister, which tallies with an increase in hostility. I have only found a single exception; and it was easy to interpret this as a confirmation of the rule. On one occasion during an analytic session I was explaining this subject to a lady, since in view of her symptom its discussion seemed to me relevant. To my astonishment she replied that she had never had such a dream. Another dream, however, occurred to her, which ostensibly had no connection with the topic - a dream which she had first dreamt when she was four years old and at that time the youngest of the family, and which she had dreamt repeatedly since: *A whole crowd of children - all her brothers, sisters and cousins of both sexes - were romping in a field. Suddenly they all grew wings, flew away and disappeared.* She had no idea what this dream meant; but it is not hard to recognize that in its original form it had been a dream of the death of all her brothers and sisters, and had been only slightly influenced by the censorship. I may venture to suggest the following analysis. On the occasion of the death of one of this crowd of children (in this instance the children of two brothers had been brought up together as a single family) the dreamer, not yet four years old at the time, must have asked some wise grown-up person what became of children when they were dead. The reply must have been: 'They grow wings and turn into little angels.' In the dream which followed upon this piece of information all the dreamer's brothers and sisters had wings like angels and - which is the main point - flew away. Our little baby-killer was left alone, strange to say: the only survivor of the whole crowd! We can hardly be wrong in supposing that the fact of the children romping in *field* before flying away points to butterflies. It is as though the child was led by the same chain of thought as the peoples of antiquity to picture the soul as having a butterfly's wings.

At this point someone will perhaps interrupt: 'Granted that children have hostile impulses towards their brothers and sisters, how can a child's mind reach such a pitch of depravity as to wish for the *death* of his rivals or of playmates stronger than himself, as though the death penalty were the only punishment for every crime?' Anyone who talks like this has failed to bear in mind that a child's idea of being 'dead' has nothing much in common with ours apart from the word. Children know nothing of the horrors of corruption, of freezing in the ice-cold grave, of the terrors of eternal nothingness - ideas which grown-up people find it so hard to tolerate, as is proved by all the myths of a future life. The fear of death has no meaning to a child; hence it is that he will play with the dreadful word and use it as a threat against a playmate: 'If you do that again, you'll die, like Franz!' Meanwhile the poor mother gives a shudder and remembers, perhaps, that the greater half of the human race fail to survive their childhood years. It was actually possible for a child, who was over eight years old at the time, coming home from a visit to the Natural History Museum, to say to his mother: 'I'm so fond of you, Mummy: when you die I'll have you stuffed and I'll keep you in this room, so that I can see you *all* the time.' So little resemblance is there between a child's idea of being dead and our own!¹

¹ [Footnote added 1909:] I was astonished to hear a highly intelligent boy often remark after the sudden death of his father: 'I know father's dead, but what I can't understand is why he doesn't come home to supper.' - [Added 1919:] Further material on this subject will be found in the first volumes of the periodical *Imago*, under the standing rubric of 'Vom wahren Wesen der Kinderseele'.

To children, who, moreover, are spared the sight of the scenes of suffering which precede death, being 'dead' means approximately the same as being 'gone' - not troubling the survivors any longer. A child makes no distinction as to how this absence is brought about: whether it is due to a journey, to a dismissal, to an estrangement, or to death.¹ If, during a child's prehistoric epoch, his nurse has been dismissed, and if soon afterwards his mother has died, the two events are superimposed on each other in a single series in his memory as revealed in analysis. When people are absent, children do not miss them with any great intensity; many mothers have learnt this to their sorrow when, after being away from home for some weeks on a summer holiday, they are met on their return by the news that the children have not once asked after their mummy. If their mother does actually make the journey to that 'undiscover'd country, from whose bourn no traveller returns', children seem at first to have forgotten her, and it is only later on that they begin to call their dead mother to mind.

Thus if a child has reasons for wishing the absence of another, there is nothing to restrain him from giving his wish the form of the other child being dead. And the psychical reaction to dreams containing death-wishes proves that, in spite of the different content of these wishes in the case of children, they are nevertheless in some way or other the same as wishes expressed in the same terms by adults.

¹ [Footnote added 1919:] An observation made by a parent who had a knowledge of psycho-analysis caught the actual moment at which his highly intelligent four-year-old daughter perceived the distinction between being 'gone' and being 'dead'. The little girl had been troublesome at meal-time and noticed that one of the maids at the pension where they were staying was looking at her askance. 'I wish Josefine was dead', was the child's comment to her father. 'Why dead?' enquired her father soothingly; 'wouldn't it do if she went away?' 'No', replied the child; 'then she'd come back again.' The unbounded self-love (the narcissism) of children regards any interference as an act of *lèse majesté*; and their feelings demand (like the Draconian code) that any such crime shall receive the one form of punishment which admits of no degrees.

If, then, a child's death-wishes against his brothers and sisters are explained by the childish egoism which makes him regard them as his rivals, how are we to explain his death-wishes against his parents, who surround him with love and fulfil his needs and whose preservation that same egoism should lead him to desire?

A solution of this difficulty is afforded by the observation that dreams of the death of parents apply with preponderant frequency to the parent who is of the same sex as the dreamer: that men, that is, dream mostly of their father's death and women of their mother's. I cannot pretend that this is universally so, but the preponderance in the direction I have indicated is so evident that it requires to be explained by a factor of general importance.¹ It is as though - to put it bluntly - a sexual preference were making itself felt at an early age: as though boys regarded their fathers and girls their mothers as their rivals in love, whose elimination could not fail to be to their advantage.

Before this idea is rejected as a monstrous one, it is as well in this case, too, to consider the real relations obtaining - this time between parents and children. We must distinguish between what the cultural standards of filial piety demand of this relation and what everyday observation shows it in fact to be. More than one occasion for hostility lies concealed in the relation between parents and children - a relation which affords the most ample opportunities for wishes to arise which cannot pass the censorship.

Let us consider first the relation between father and son. The sanctity which we attribute to the rules laid down in the Decalogue has, I think, blunted our powers of perceiving the real facts. We seem scarcely to venture to observe that the majority of mankind disobey the Fifth Commandment. Alike in the lowest and in the highest strata of human society filial piety is wont to give way to other interests. The obscure information which is brought to us by mythology and legend from the *primaeval* ages of human society gives an unpleasing picture of the father's despotic power and of the ruthlessness with which he made use of it. Kronos devoured his children, just as the wild boar devours the sow's litter; while Zeus emasculated his father² and made himself ruler in his place. The more unrestricted was the rule of the father in the ancient family, the more must the son, as his destined successor, have found himself in the position of an enemy, and the more impatient must he have been to become ruler himself though his father's death. Even in our middle-class families fathers are as a rule inclined to refuse their sons independence and the means necessary to secure it and thus to foster the growth of the germ of hostility which is inherent in their relation. A physician will often be in a position to notice how a son's grief at the loss of his father cannot suppress his satisfaction at having at length won his freedom. In our society to-day fathers are apt to cling desperately to what is left of a now sadly antiquated *protestas patris familias*; and an author who, like Ibsen, brings the immemorial struggle between fathers and sons into prominence in his writings may be certain of producing his effect.

¹ [Footnote added 1925:] The situation is often obscured by the emergence of a self-punitive impulse, which threatens the dreamer, by way of a moral reaction, with the loss of the parent whom he loves.

² [Footnote added 1909:] Or so he is reported to have done according to some myths. According to others, emasculation was only carried out by Kronos on his father Uranus. For the mythological significance of this theme, cf. Rank, 1909, [added 1914:] and Rank, 1912c, Chapter IX, Section 2.

Occasions for conflict between a daughter and her mother arise when the daughter begins to grow up and long for sexual liberty, but finds herself under her mother's tutelage; while the mother, on the other hand, is warned by her daughter's growth that the time has come when she herself must abandon her claims to sexual satisfaction.

All of this is patent to the eyes of everyone. But it does not help us in our endeavour to explain dreams of a parent's death in people whose piety towards their parents has long been unimpeachably established. Previous discussions, moreover, will have prepared us to learn that the death-wish against parents dates back to earliest childhood.

This supposition is confirmed with a certainty beyond all doubt in the case of psychoneurotics when they are subjected to analysis. We learn from them that a child's sexual wishes - if in their embryonic stage they deserve to be so described - awaken very early, and that a girl's first affection is for her father and a boy's first childish desires are for his mother. Accordingly, the father becomes a disturbing rival to the boy and the mother to the girl; and I have already shown in the case of brothers and sisters how easily such feelings can lead to a death-wish. The parents too give evidence as a rule of sexual partiality: a natural predilection usually sees to it that a man tends to spoil his little daughters, while his wife take her sons' part; though both of them, where their judgement is not disturbed by the magic of sex, keep a strict eye upon their children's education. The child is very well aware of this partiality and turns against that one of his parents who is opposed to showing it. Being loved by an adult does not merely bring a child the satisfaction of a special need; it also means that he will get what he wants in every other respect as well. Thus he will be following his own sexual instinct and at the same time giving fresh strength to the inclination shown by his parents if his choice between them falls in with theirs.

The signs of these infantile preferences are for the most part overlooked; yet some of them are to be observed even after the first years of childhood. An eight-year-old girl of my acquaintance, if her mother is called away from the table, makes use of the occasion to proclaim herself her successor: 'I'm going to be Mummy now. Do you want some more greens, Karl? Well, help yourself, then!' and so on. A particularly gifted and lively girl of four, in whom this piece of child psychology is especially transparent, declared quite openly: 'Mummy can go away now. Then Daddy must marry me and I'll be his wife.' Such a wish occurring in a child is not in the least inconsistent with her being tenderly attached to her mother. If a little boy is allowed to sleep beside his mother when his father is away from home, but has to go back to the nursery and to someone of whom he is far less fond as soon as his father returns, he may easily begin to form a wish that his father should *always* be away, so that he himself could keep his place beside his dear, lovely Mummy. One obvious way of attaining this wish would be if his father were dead; for the child has learnt one thing by experience namely that 'dead' people, such as Granddaddy, are always away and never come back.

Though observations of this kind on small children fit in perfectly with the interpretation I have proposed, they do not carry such complete conviction as is forced upon the physician by psycho-analyses of adult neurotics. In the latter case dreams of the sort we are considering are introduced into the analysis in such a context that it is impossible to avoid interpreting them as *wishful* dreams.

One day one of my women patients was in a distressed and tearful mood. 'I don't want ever to see my relations again', she said, 'they must think me horrible.' She then went on, with almost no transition, to say that she remembered a dream, though of course she had no idea what it meant. When she was four years old she had a dream that *a lynx or a fox was walking on the roof; then something had fallen down or she had fallen down; and then her mother was carried out of the house dead* - and then she wept bitterly. I told her that this dream must mean that when she was a child she had wished she could see her mother dead, and that it must be on account of the dream that she felt her relations must think her horrible. I had scarcely said this when she produced some material which threw light on the dream. 'Lynx eye' was a term of abuse that had been thrown at her by a street-urchin when she was a very small child. When she was three years old, a tile off the roof had fallen on her mother's head and made it bleed violently.

I once had an opportunity of making a detailed study of a young woman who passed through a variety of psychical conditions. Her illness began with a state of confusional excitement during which she displayed a quite special aversion to her mother, hitting and abusing her whenever she came near her bed, while at the same period she was docile and affectionate towards a sister who was many years her senior. This was followed by a state in which she was lucid but somewhat apathetic and suffered from badly disturbed sleep. It was during this phase that I began treating her and analysing her dreams. An immense number of these dreams were concerned, with a greater or less degree of disguise, with the death of her mother: at one time she would be attending an old woman's funeral, at another she and her sister would be sitting at table dressed in mourning. There could be no question as to the meaning of these dreams. As her condition improved still further, hysterical phobias developed. The most tormenting of these was a fear that something might have happened to her mother. She was obliged to hurry home, wherever she might be, to convince herself that her mother was still alive. This case, taken in conjunction with what I had learnt from other sources, was highly instructive: it exhibited, translated as it were into different languages, the various ways in which the psychical apparatus reacted to one and the same exciting idea. In the confusional state, in which, as I believe, the second psychical agency was overwhelmed by the normally suppressed first one, her unconscious hostility to her mother found a powerful *motor* expression. When the calmer condition set in, when the rebellion was suppressed and the domination of the censorship re-established, the only region left open in which her hostility could realize the wish for her mother's death was that of dreaming. When a normal state was still more firmly established, it led to the production of her exaggerated worry about her mother as a hysterical counter-reaction and defensive phenomenon. In view of this it is no longer hard to understand why hysterical girls are so often attached to their mothers with such exaggerated affection.

On another occasion I had an opportunity of obtaining a deep insight into the unconscious mind of a young man whose life was made almost impossible by an obsessional neurosis. He was unable to go out into the street because he was tortured by the fear that he would kill everyone he met. He spent his days in preparing his alibi in case he might be charged with one of the murders committed in the town. It is unnecessary to add that he was a man of equally high morals and education. The analysis (which, incidentally, led to his recovery) showed that the basis of this distressing obsession was an impulse to murder his somewhat over-severe father. This impulse, to his astonishment, had been consciously expressed when he was seven years old, but it had, of course, originated much earlier in his childhood. After his father's painful illness and death, the patient's obsessional self-reproaches appeared - he was in his thirty-first year at the time - taking the shape of a phobia transferred on to strangers. A person, he felt, who was capable of wanting to push his own father over a precipice from the top of a mountain was not to be trusted to respect the lives of those less closely related to him; he was quite right to shut himself up in his room.

In my experience, which is already extensive, the chief part in the mental lives of all children who later become psychoneurotics is played by their parents. Being in love with the one parent and hating the other are among the essential constituents of the stock of psychical impulses which is formed at that time and which is of such importance in determining the symptoms of the later neurosis. It is not my belief, however, that psychoneurotics differ sharply in this respect from other human beings who remain normal - that they are able, that is, to create something absolutely new and peculiar to themselves. It is far more probable - and this is confirmed by occasional observations on normal children - that they are only distinguished by exhibiting on a magnified scale feelings of love and hatred to their parents which occur less obviously and less intensely in the minds of most children.

This discovery is confirmed by a legend that has come down to us from classical antiquity: a legend whose profound and universal power to move can only be understood if the hypothesis I have put forward in regard to the psychology of children has an equally universal validity. What I have in mind is the legend of King Oedipus and Sophocles' drama which bears his name.

Oedipus, son of Laius, King of Thebes, and of Jocasta, was exposed as an infant because an oracle had warned Laius that the still unborn child would be his father's murderer. The child was rescued, and grew up as a prince in an alien court, until, in doubts as to his origin, he too questioned the oracle and was warned to avoid his home since he was destined to murder his father and take his mother in marriage. On the road leading away from what he believed was his home, he met King Laius and slew him in a sudden quarrel. He came next to Thebes and solved the riddle set him by the Sphinx who barred his way. Out of gratitude the Thebans made him their king and gave him Jocasta's hand in marriage. He reigned long in peace and honour, and she who, unknown to him, was his mother bore him two sons and two daughters. Then at last a plague broke out and the Thebans made enquiry once more of the oracle. It is at this point that Sophocles' tragedy opens. The messengers bring back the reply that the plague will cease when the murderer of Laius has been driven from the land.

But he, where is he? Where shall now be read
The fading record of this ancient guilt?

The action of the play consists in nothing other than the process of revealing, with cunning delays and ever-mounting excitement - a process that can be likened to the work of a psycho-analysis - that Oedipus himself is the murderer of Laius, but further that he is the son of the murdered man and of Jocasta. Appalled at the abomination which he has unwittingly perpetrated, Oedipus blinds himself and forsakes his home. The oracle has been fulfilled.

Oedipus Rex is what is known as a tragedy of destiny. Its tragic effect is said to lie in the contrast between the supreme will of the gods and the vain attempts of mankind to escape the evil that threatens them. The lesson which, it is said, the deeply moved spectator should learn from the tragedy is submission to the divine will and realization of his own impotence. Modern dramatists have accordingly tried to achieve a similar tragic effect by weaving the same contrast into a plot invented by themselves. But the spectators have looked on unmoved while a curse or an oracle was fulfilled in spite of all the efforts of some innocent man: later tragedies of destiny have failed in their effect.

If *Oedipus Rex* moves a modern audience no less than it did the contemporary Greek one, the explanation can only be that its effect does not lie in the contrast between destiny and human will, but is to be looked for in the particular nature of the material on which that contrast is exemplified. There must be something which makes a voice within us ready to recognize the compelling force of destiny in the *Oedipus*, while we can dismiss as merely arbitrary such dispositions as are laid down in *Die Ahnfrau* or other modern tragedies of destiny. And a factor of this kind is in fact involved in the story of King Oedipus. His destiny moves us only because it might have been ours - because the oracle laid the same curse upon us before our birth as upon him. It is the fate of all of us, perhaps, to direct our first sexual impulse towards our mother and our first hatred and our first murderous wish against our father. Our dreams convince us that that is so. King Oedipus, who slew his father Laius and married his mother Jocasta, merely shows us the fulfilment of our own childhood wishes. But, more fortunate than he, we have meanwhile succeeded, in so far as we have not become psychoneurotics, in detaching our sexual impulses from our mothers and in forgetting our jealousy of our fathers. Here is one in whom these primæval wishes of our childhood have been fulfilled, and we shrink back from him with the whole force of the repression by which those wishes have since that time been held down within us. While the poet, as he unravels the past, brings to light the guilt of Oedipus, he is at the same time compelling us to recognize our own inner minds, in which those same impulses, though suppressed, are still to be found. The contrast with which the closing Chorus leaves us confronted -

. . . Fix on Oedipus your eyes,
Who resolved the dark enigma, noblest champion and most wise.
Like a star his envied fortune mounted beaming far and wide:
Now he sinks in seas of anguish, whelmed beneath a raging tide . . .

- strikes as a warning at ourselves and our pride, at us who since our childhood have grown so wise and so mighty in our own eyes. Like Oedipus, we live in ignorance of these wishes, repugnant to morality, which have been forced upon us by Nature, and after their revelation we may all of us well seek to close our eyes to the scenes of our childhood.¹

¹ [Footnote added 1914:] None of the findings of psycho-analytic research has provoked such embittered denials, such fierce opposition - or such amusing contortions - on the part of critics as this indication of the childhood impulses towards incest which persist in the unconscious. An attempt has even been made recently to make out, in the face of all experience, that the incest should only be taken as 'symbolic'. - Ferenczi (1912) has proposed an ingenious 'over-interpretation' of the Oedipus myth, based on a passage in one of Schopenhauer's letters. - [Added 1919:] Later studies have shown that the 'Oedipus complex', which was touched upon for the first time in the above paragraphs in the *Interpretation of Dreams*, throws a light of undreamt-of importance on the history of the human race and the evolution of religion and morality - (See my *Totem and Taboo*, 1912-13.)

There is an unmistakable indication in the text of Sophocles' tragedy itself that the legend of Oedipus sprang from some *primaeval* dream-material which had as its content the distressing disturbance of a child's relation to his parents owing to the first stirrings of sexuality. At a point when Oedipus, though he is not yet enlightened, has begun to feel troubled by his recollection of the oracle, Jocasta consoles him by referring to a dream which many people dream, though, as she thinks, it has no meaning:

Many a man ere now in dreams hath lain
With her who bare him. He hath least annoy
Who with such omens troubleth not his mind.

To-day, just as then, many men dream of having sexual relations with their mothers, and speak of the fact with indignation and astonishment. It is clearly the key to the tragedy and the complement to the dream of the dreamer's father being dead. The story of Oedipus is the reaction of the imagination to these two typical dreams. And just as these dreams, when dreamt by adults, are accompanied by feelings of repulsion, so too the legend must include horror and self-punishment. Its further modification originates once again in a misconceived secondary revision of the material, which has sought to exploit it for theological purposes. (Cf. the dream-material in dreams of exhibiting, p. 721 f.) The attempt to harmonize divine omnipotence with human responsibility must naturally fail in connection with this subject-matter just as with any other.

Another of the great creations of tragic poetry, Shakespeare's *Hamlet*, has its roots in the same soil as *Oedipus Rex*. But the changed treatment of the same material reveals the whole difference in the mental life of these two widely separated epochs of civilization: the secular advance of repression in the emotional life of mankind. In the *Oedipus* the child's wishful phantasy that underlies it is brought into the open and realized as it would be in a dream. In *Hamlet* it remains repressed; and - just as in the case of a neurosis - we only learn of its existence from its inhibiting consequences. Strangely enough, the overwhelming effect produced by the more modern tragedy has turned out to be compatible with the fact that people have remained completely in the dark as to the hero's character. The play is built up on Hamlet's hesitations over fulfilling the task of revenge that is assigned to him; but its text offers no reasons or motives for these hesitations and an immense variety of attempts at interpreting them have failed to produce a result. According to the view which was originated by Goethe and is still the prevailing one to-day, Hamlet represents the type of man whose power of direct action is paralysed by an excessive development of his intellect. (He is 'sicklied o'er with the pale cast of thought.') According to another view, the dramatist has tried to portray a pathologically irresolute character which might be classed as neurasthenic. The plot of the drama shows us, however, that Hamlet is far from being represented as a person incapable of taking any action. We see him doing so on two occasions: first in a sudden outburst of temper, when he runs his sword through the eavesdropper behind the arras, and secondly in a premeditated and even crafty fashion, when, with all the callousness of a Renaissance prince, he sends the two courtiers to the death that had been planned for himself. What is it, then, that inhibits him in fulfilling the task set him by his father's ghost? The answer, once again, is that it is the peculiar nature of the task. Hamlet is able to do anything - except take vengeance on the man who did away with his father and took that father's place with his mother, the man who shows him the repressed wishes of his own childhood realized. Thus the loathing which should drive him on to revenge is replaced in him by self-reproaches, by scruples of conscience, which remind him that he himself is literally no better than the sinner whom he is to punish. Here I have translated into conscious terms what was bound to remain unconscious in Hamlet's mind; and if any one is inclined to call him a hysteric, I can only accept the fact as one that is implied by my interpretation. The distaste for sexuality expressed by Hamlet in his conversation with Ophelia fits in very well with this: the same distaste which was destined to take possession of the poet's mind more and more during the years that followed, and which reached its extreme expression in *Timon of Athens*. For it can of course only be the poet's own mind which confronts us in Hamlet. I observe in a book on Shakespeare by Georg Brandes (1896) a statement that *Hamlet* was written immediately after the death of Shakespeare's father (in 1601), that is, under the immediate impact of his bereavement and, as we may well assume, while his childhood feelings about his father had been freshly revived. It is known, too, that Shakespeare's own son who died at an early age bore the name of 'Hamnet', which is identical with 'Hamlet'. Just as *Hamlet* deals with the relation of a son to his parents, so *Macbeth* (written at approximately the same period) is concerned with the subject of childlessness. But just as all neurotic symptoms, and, for that matter, dreams, are capable of being 'over-interpreted' and indeed need to be, if they are to be fully understood, so all genuinely creative writings are the product of more than a single motive and more than a single impulse in the poet's mind, and are open to more than a single interpretation. In what I have written I have only attempted to interpret the deepest layer of impulses in the mind of the creative writer.¹

¹ [Footnote added 1919:] The above indications of a psycho-analytic explanation of *Hamlet* have since been amplified by Ernest Jones and defended against the alternative views put forward in the literature of the subject. (See Jones, 1910a .) - [Added 1930:] Incidentally, I have in the meantime ceased to believe that the author of Shakespeare's works was the man from Stratford. - [Added 1919:] Further attempts at an analysis of *Macbeth* will be found in a paper of mine and in one by Jekels (1917).

I cannot leave the subject of typical dreams of the death of loved relatives, without adding a few more words to throw light on their significance for the theory of dreams in general. In these dreams we find the highly unusual condition realized of a dream-thought formed by a repressed wish entirely eluding censorship and passing into the dream without modification. There must be special factors at work to make this event possible, and I believe that the occurrence of these dreams is facilitated by two such factors. Firstly, there is no wish that seems more remote from us than this one: 'we couldn't even *dream*' - so we believe - of wishing such a thing. For this reason the dream-censorship is not armed to meet such a monstrosity, just as Solon's penal code contained no punishment for parricide. Secondly, in this case the repressed and unsuspected wish is particularly often met half-way by a residue from the previous day in the form of a *worry* about the safety of the person concerned. This worry can only make its way into the dream by availing itself of the corresponding wish; while the wish can disguise itself behind the worry that has become active during the day. We may feel inclined to think that things are simpler than this and that one merely carries on during the night and in dreams with what one has been turning over in one's mind during the day; but if so we shall be leaving dreams of the death of people of whom the dreamer is fond completely in the air and without any connection with our explanation of dreams in general, and we shall thus be clinging quite unnecessarily to a riddle which is perfectly capable of solution.

It is also instructive to consider the relation of these dreams to anxiety-dreams. In the dreams we have been discussing, a repressed wish has found a means of evading censorship - and the distortion which censorship involves. The invariable concomitant is that painful feelings are experienced in the dream. In just the same way anxiety-dreams only occur if the censorship has been wholly or partly overpowered; and, on the other hand, the overpowering of the censorship is facilitated if anxiety has already been produced as an immediate sensation arising from somatic sources. We can thus plainly see the purpose for which the censorship exercises its office and brings about the distortion of dreams: it does so *in order to prevent the generation of anxiety or other forms of distressing affect*.

I have spoken above of the egoism of children's minds, and I may now add, with a hint at a possible connection between the two facts, that dreams have the same characteristic. All of them are completely egoistic: the beloved ego appears in all of them, even though it may be disguised. The wishes that are fulfilled in them are invariably the ego's wishes, and if a dream seems to have been provoked by an altruistic interest, we are only being deceived by appearances. Here are a few analyses of instances which seem to contradict this assertion.

I

A child of under four years old reported having dreamt that *he had seen a big dish with a big joint of roast meat and vegetables on it. All at once the joint had been eaten up - whole and without being cut up. He had not seen the person who ate it.*¹

Who can the unknown person have been whose sumptuous banquet of meat was the subject of the little boy's dream? His experiences during the dream-day must enlighten us on the subject. By doctor's orders he had been put on a milk diet for the past few days. On the evening of the dream-day he had been naughty, and as a punishment he had been sent to bed without his supper. He had been through this hunger-cure once before and had been very brave about it. He knew he would get nothing, but would not allow himself to show by so much as a single word that he was hungry. Education had already begun to have an effect on him: it found expression in this dream, which exhibits the beginning of dream-distortion. There can be no doubt that the person whose wishes were aimed at this lavish meal - a meat meal, too - was himself. But since he knew he was not allowed it, he did not venture to sit down to the meal himself, as hungry children do in dreams. (Cf. my little daughter Anna's dream of strawberries on p. 628.) The person who ate the meal remained anonymous.

II

I dreamt one night that I saw in the window of a book-shop a new volume in one of the series of monographs for connoisseurs which I am in the habit of buying - monographs on great artists, on world history, on famous cities, etc. *The new series was called 'Famous Speakers' or 'Speeches' and its first volume bore the name of Dr. Lecher.*

When I came to analyse this, it seemed to me improbable that I should be concerned in my dreams with the fame of Dr. Lecher, the non-stop speaker of the German Nationalist obstructionists in Parliament. The position was that a few days earlier I had taken on some new patients for psychological treatment, and was now obliged to talk for ten or eleven hours every day. So it was I myself who was a non-stop speaker.

¹ The appearance in dreams of things of great size and in great quantities and amounts, and of exaggeration generally, may be another childish characteristic. Children have no more ardent wish than to be big and grown-up and to get as much of things as grown-up people do. They are hard to satisfy, know no such word as 'enough' and insist insatiably on a repetition of things which they have enjoyed or whose taste they liked. It is only the civilizing influence of education that teaches them moderation and how to be content or resigned. Everyone knows that neurotics are equally inclined to be extravagant and immoderate.

III

Another time I had a dream that a man I knew on the staff of the University said to me: '*My son, the Myops.*' Then followed a dialogue made up of short remarks and rejoinders. After this, however, there was yet a third piece of dream in which I myself and my sons figured. So far as the dream's latent content was concerned, Professor M. and his son were men of straw - a mere screen for me and my eldest son. I shall have to return to this dream later, on account of another of its features.

IV

The dream which follows is an instance of really low egoistic feelings concealed behind affectionate worry.

My friend Otto was looking ill. His face was brown and he had protruding eyes.

Otto is my family doctor, and I owe him more than I can ever hope to repay: he has watched over my children's health for many years, he has treated them successfully when they have been ill, and, in addition, whenever circumstances have given him an excuse, he has given them presents. He had visited us on the dream-day, and my wife had remarked that he looked tired and strained. That night I had my dream, which showed him with some of the signs of *Basedow's* disease. Anyone who interprets this dream without regard for my rules will conclude that I was worried about my friend's health and that this worry was realized in the dream. This would not only contradict my assertion that dreams are wish-fulfilments, but my other assertion, too, that they are accessible only to egoistic impulses. But I should be glad if anyone interpreting the dream in this way would be good enough to explain to me why my fears on Otto's behalf should have lighted on *Basedow's* disease - a diagnosis for which his actual appearance gives not the slightest ground. My analysis, on the other hand, brought up the following material from an occurrence six years earlier. A small group of us, which included Professor R., were driving in pitch darkness through the forest of N., which lay some hours' drive from the place at which we were spending our summer holidays. The coachman, who was not perfectly sober, spilt us, carriage and all, over an embankment, and it was only by a piece of luck that we all escaped injury. We were obliged, however, to spend the night in a neighbouring inn, at which the news of our accident brought us a lot of sympathy. A gentleman, with unmistakable signs of *Basedow's* disease - incidentally, just as in the dream, only the brown discoloration of the skin of the face and the protruding eyes, but no goitre - placed himself entirely at our disposal and asked what he could do for us. Professor R. replied in his decisive manner: 'Nothing except to lend me a night-shirt.' To which the fine gentleman rejoined: 'I'm sorry, but I can't do that', and left the room.

As I continued my analysis, it occurred to me that *Basedow* was the name not only of a physician but also of a famous educationalist. (In my waking state I no longer felt quite so certain about this.) But my friend Otto was the person whom I had asked to watch over my children's physical education, especially at the age of puberty (hence the night-shirt), in case anything happened to me. By giving my friend Otto in the dream the symptoms of our noble helper, I was evidently saying that if anything happened to me he would do just as little for the children as Baron L. had done on that occasion in spite of his kind offers of assistance. This seems to be sufficient evidence of the egoistic lining of the dream.¹

But where was its wish-fulfilment to be found? Not in my avenging myself on my friend Otto, whose fate it seems to be to be ill-treated in my dreams; but in the following consideration. At the same time as I represented Otto in the dream as Baron L., I had identified myself with someone else, namely Professor R.; for just as in the anecdote R. had made a request to Baron L., so I had made a request to Otto. And that is the point. Professor R., with whom I should really not venture to compare myself in the ordinary way, resembled me in having followed an independent path outside the academic world and had only achieved his well-merited title late in life. So once again I was wanting to be a Professor! Indeed the words 'late in life' were themselves a wish-fulfilment; for they implied that I should live long enough to see my boys through the age of puberty myself.

¹ [Footnote added 1911:] When Ernest Jones was giving a scientific lecture on the egoism of dreams before an American audience, a learned lady objected to this unscientific generalization, saying that the author of the present work could only judge of the dreams of Austrians and had no business to speak of the dreams of Americans. So far as she was concerned, she was certain that all her dreams were strictly altruistic.- [Added 1925:] By way of excuse for this patriotic lady, I may remark that the statement that dreams are entirely egoistic must not be misunderstood. Since anything whatever that occurs in preconscious thought can pass into a dream (whether into its actual content or into the latent dream-thoughts) that possibility is equally open to altruistic impulses. In the same way, an affectionate or erotic impulse towards someone else, if it is present in the unconscious, can appear in a dream. The truth in the assertion made in the text above is thus restricted to the fact that among the unconscious instigators of a dream we very frequently find egoistic impulses which seem to have been overcome in waking life.

I have no experience of my own of other kinds of typical dreams, in which the dreamer finds himself flying through the air to the accompaniment of agreeable feelings or falling with feelings of anxiety; and whatever I have to say on the subject is derived from psycho-analyses. The information provided by the latter forces me to conclude that these dreams, too, reproduce impressions of childhood; they relate, that is, to games involving movement, which are extraordinarily attractive to children. There cannot be a single uncle who has not shown a child how to fly by rushing across the room with him in his outstretched arms, or who has not played at letting him fall by riding him on his knee and then suddenly stretching out his leg, or by holding him up high and then suddenly pretending to drop him. Children are delighted by such experiences and never tire of asking to have them repeated, especially if there is something about them that causes a little fright or giddiness. In after years they repeat these experiences in dreams; but in the dreams they leave out the hands which held them up, so that they float or fall unsupported. The delight taken by young children in games of this kind (as well as in swings and see-saws) is well known; and when they come to see acrobatic feats in a circus their memory of such games is revived.¹ Hysterical attacks in boys sometimes consist merely in reproductions of feats of this kind, carried out with great skill. It not uncommonly happens that these games of movement, though innocent in themselves, give rise to sexual feelings.² Childish 'romping', if I may use a word which commonly describes all such activities, is what is being repeated in dreams of flying, falling, giddiness and so on; while the pleasurable feelings attached to these experiences are transformed into anxiety. But often enough, as every mother knows, romping among children actually ends in squabbling and tears.

Thus I have good grounds for rejecting the theory that what provokes dreams of flying and falling is the state of our tactile feelings during sleep or sensations of the movement of our lungs, and so on. In my view these sensations are themselves reproduced as part of the memory to which the dream goes back: that is to say, they are part of the *content* of the dream and not its source.

¹ [Footnote added 1925:] Analytic research has shown us that in addition to pleasure derived from the organs concerned, there is another factor which contributes to the delight taken by children in acrobatic performances and to their repetition in hysterical attacks. This other factor is a memory-image, often unconscious, of an observation of sexual intercourse, whether between human beings or animals.

² A young medical colleague, who is quite free from any kind of nervous trouble, has given me the following information on this point: 'I know from my own experience that in my childhood I had a peculiar sensation in my genitals when I was on a swing and especially when the downward motion reached its greatest momentum. And though I cannot say I really enjoyed this sensation I must describe it as a pleasurable one.' - Patients have often told me that the first pleasurable erections that they can remember occurred in their boyhood while they were climbing about. - Psycho-analysis makes it perfectly certain that the first sexual impulses frequently have their roots in games involving romping and wrestling played during childhood.

I cannot, however, disguise from myself that I am unable to produce any complete explanation of this class of typical dreams. My material has left me in the lurch precisely at this point. I must, however, insist upon the general assertion that all the tactile and motor sensations which occur in these typical dreams are called up immediately there is any psychical reason for making use of them and that they can be disregarded when no such need for them arises. I am also of the opinion that the relation of these dreams to infantile experiences has been established with certainty from the indications I have found in the analyses of psychoneurotics. I am not able to say, however, what other meanings may become attached to the recollection of such sensations in the course of later life - different meanings, perhaps, in every individual case, in spite of the typical appearance of the dreams; and I should be glad to be able to fill up the gap by a careful analysis of clear instances. If anyone feels surprised that, in spite of the frequency precisely of dreams of flying, falling and pulling out teeth, etc., I should be complaining of lack of material on this particular topic, I must explain that I myself have not experienced any dreams of the kind since I turned my attention to the subject of dream-interpretation. The dreams of neurotics, moreover, of which I might otherwise avail myself, cannot always be interpreted not, at least, in many cases, so as to reveal the whole of their concealed meaning; a particular psychical force, which was concerned with the original constructing of the neurosis and is brought into operation once again when attempts are made at resolving it, prevents us from interpreting such dreams down to their last secret.

(7) EXAMINATION DREAMS

Everyone who has passed the matriculation examination at the end of his school studies complains of the obstinacy with which he is pursued by anxiety-dreams of having failed, or of being obliged to take the examination again, etc. In the case of those who have obtained a University degree this typical dream is replaced by another one which represents them as having failed in their University Finals; and it is in vain that they object, even while they are still asleep, that for years they have been practising medicine or working as University lecturers or heads of offices. The ineradicable memories of the punishments that we suffered for our evil deeds in childhood become active within us once more and attach themselves to the two crucial points in our studies - the '*dies irae, dies illa*' of our stiffest examinations. The 'examination anxiety' of neurotics owes its intensification to these same childhood fears. After we have ceased to be school-children, our punishments are no longer inflicted on us by our parents or by those who brought us up or later by our schoolmasters. The relentless causal chains of real life take charge of our further education, and now we dream of Matriculation or Finals (and who has not trembled on those occasions, even if he was well-prepared for the examination?) whenever, having done something wrong or failed to do something properly, we expect to be punished by the event - whenever, in short, we feel the burden of responsibility.

For a further explanation of examination dreams I have to thank an experienced colleague, who once declared at a scientific meeting that so far as he knew dreams of Matriculation only occur in people who have successfully passed it and never in people who have failed in it. It would seem, then, that anxious examination dreams (which, as has been confirmed over and over again, appear when the dreamer has some responsible activity ahead of him next day and is afraid there may be a fiasco) search for some occasion in the past in which great anxiety has turned out to be unjustified and has been contradicted by the event. This, then, would be a very striking instance of the content of a dream being misunderstood by the waking agency. What is regarded as an indignant protest against the dream: 'But I'm a doctor, etc., already!' would in reality be the consolation put forward by the dream, and would accordingly run: 'Don't be afraid of tomorrow! Just think how anxious you were before your Matriculation, and yet nothing happened to you. You're a doctor, etc., already.' And the anxiety which is attributed to the dream would really have arisen from the day's residues.

Such tests as I have been able to make of this explanation on myself and on other people, though they have not been sufficiently numerous, have confirmed its validity. For instance, I myself failed in Forensic Medicine in my Finals; but I have never had to cope with this subject in dreams, whereas I have quite often been examined in Botany, Zoology or Chemistry. I went in for the examination in these subjects with well-founded anxiety; but, whether by the grace of destiny or of the examiners, I escaped punishment. In my dreams of school examinations, I am invariably examined in History, in which I did brilliantly - though only, it is true, because my kindly master (the one-eyed benefactor of another dream, see [p. 531](#)) did not fail to notice that on the paper of questions which I handed him back I had run my finger-nail through the middle one of the three questions included, to warn him not to insist upon that particular one. One of my patients, who decided not to sit for his Matriculation the first time but passed it later, and who subsequently failed in his army examination and never got a commission, has told me that he often dreams of the former of these examinations but never of the latter.

The interpretation of examination dreams is faced by the difficulty which I have already referred to as characteristic of the majority of typical dreams. It is but rarely that the material with which the dreamer provides us in associations is sufficient to interpret the dream. It is only by collecting a considerable number of examples of such dreams that we can arrive at a better understanding of them. Not long ago I came to the conclusion that the objection, 'You're a doctor, etc., already', does not merely conceal a consolation but also signifies a reproach. This would have run: 'You're quite old now, quite far advanced in life, and yet you go on doing these stupid, childish things.' This mixture of self-criticism and consolation would thus correspond to the latent content of examination dreams. If so, it would not be surprising if the self-reproaches for being 'stupid' and 'childish' in these last examples referred to the repetition of reprehensible sexual acts.

Wilhelm Stekel, who put forward the first interpretation of dreams of Matriculation [*'Matura'*], was of the opinion that they regularly related to sexual tests and sexual maturity. My experience has often confirmed his view.

CHAPTER VI

THE DREAM-WORK

Every attempt that has hitherto been made to solve the problem of dreams has dealt directly with their *manifest* content as it is presented in our memory. All such attempts have endeavoured to arrive at an interpretation of dreams from their manifest content or (if no interpretation was attempted) to form a judgement as to their nature on the basis of that same manifest content. We are alone in taking something else into account. We have introduced a new class of psychical material between the manifest content of dreams and the conclusions of our enquiry: namely, their *latent* content, or (as we say) the 'dream-thoughts', arrived at by means of our procedure. It is from these dream-thoughts and not from a dream's manifest content that we disentangle its meaning. We are thus presented with a new task which had no previous existence: the task, that is, of investigating the relations between the manifest content of dreams and the latent dream-thoughts, and of tracing out the processes by which the latter have been changed into the former.

The dream-thoughts and the dream-content are presented to us like two versions of the same subject-matter in two different languages. Or, more properly, the dream-content seems like a transcript of the dream-thoughts into another mode of expression, whose characters and syntactic laws it is our business to discover by comparing the original and the translation. The dream-thoughts are immediately comprehensible, as soon as we have learnt them. The dream-content, on the other hand, is expressed as it were in a pictographic script, the characters of which have to be transposed individually into the language of the dream-thoughts. If we attempted to read these characters according to their pictorial value instead of according to their symbolic relation, we should clearly be led into error. Suppose I have a picture-puzzle, a rebus, in front of me. It depicts a house with a boat on its roof, a single letter of the alphabet, the figure of a running man whose head has been conjured away, and so on. Now I might be misled into raising objections and declaring that the picture as a whole and its component parts are nonsensical. A boat has no business to be on the roof of a house, and a headless man cannot run. Moreover, the man is bigger than the house; and if the whole picture is intended to represent a landscape, letters of the alphabet are out of place in it since such objects do not occur in nature. But obviously we can only form a proper judgement of the rebus if we put aside criticisms such as these of the whole composition and its parts and if, instead, we try to replace each separate element by a syllable or word that can be represented by that element in some way or other. The words which are put together in this way are no longer nonsensical but may form a poetical phrase of the greatest beauty and significance. A dream is a picture puzzle of this sort and our predecessors in the field of dream interpretation have made the mistake of treating the rebus as a pictorial composition: and as such it has seemed to them nonsensical and worthless.

(A)

THE WORK OF CONDENSATION

The first thing that becomes clear to anyone who compares the dream-content with the dream-thoughts is that a work of *condensation* on a large scale has been carried out. Dreams are brief, meagre and laconic in comparison with the range and wealth of the dream-thoughts. If a dream is written out it may perhaps fill half a page. The analysis setting out the dream-thoughts underlying it may occupy six, eight or a dozen times as much space. This relation varies with different dreams; but so far as my experience goes its direction never varies. As a rule one underestimates the amount of compression that has taken place, since one is inclined to regard the dream-thoughts that have been brought to light as the complete material, whereas if the work of interpretation is carried further it may reveal still more thoughts concealed behind the dream. I have already had occasion to point out that it is in fact never possible to be sure that a dream has been completely interpreted. Even if the solution seems satisfactory and without gaps, the possibility always remains that the dream may have yet another meaning. Strictly speaking, then, it is impossible to determine the amount of condensation.

There is an answer, which at first sight seems most plausible, to the argument that the great lack of proportion between the dream-content and the dream-thoughts implies that the psychical material has undergone an extensive process of condensation in the course of the formation of the dream. We very often have an impression that we have dreamt a great deal all through the night and have since forgotten most of what we dreamt. On this view, the dream which we remember when we wake up would only be a fragmentary remnant of the total dream-work; and this, if we could recollect it in its entirety, might well be as extensive as the dream-thoughts. There is undoubtedly some truth in this: there can be no question that dreams can be reproduced most accurately if we try to recall them as soon as we wake up and that our memory of them becomes more and more incomplete towards evening. But on the other hand it can be shown that the impression that we have dreamt a great deal more than we can reproduce is very often based on an illusion, the origin of which I shall discuss later. Moreover the hypothesis that condensation occurs during the dream-work is not affected by the possibility of dreams being forgotten, since this hypothesis is proved to be correct by the quantities of ideas which are related to each individual piece of the dream which has been retained. Even supposing that a large piece of the dream has escaped recollection, this may merely have prevented our having access to another group of dream-thoughts. There is no justification for supposing that the lost pieces of the dream would have related to the same thoughts which we have already reached from the pieces of the dream that have survived.¹

¹ [Footnote added 1914:] The occurrence of condensation in dreams has been hinted at by many writers. Du Prel (1885, 85) has a passage in which he says it is absolutely certain that there has been a process of condensation of the groups of ideas in dreams.

In view of the very great number of associations produced in analysis to each individual element of the content of a dream, some readers may be led to doubt whether, as a matter of principle, we are justified in regarding as part of the dream-thoughts all the associations that occur to us during the subsequent analysis - whether we are justified, that is, in supposing that all these thoughts were already active during the state of sleep and played a part in the formation of the dream. Is it not more probable that new trains of thought have arisen in the course of the analysis which had no share in forming the dream? I can only give limited assent to this argument. It is no doubt true that some trains of thought arise for the first time during the analysis. But one can convince oneself in all such cases that these new connections are only set up between thoughts which were already linked in some other way in the dream-thoughts. The new connections are, as it were, loop-lines or short-circuits, made possible by the existence of other and deeper-lying connecting paths. It must be allowed that the great bulk of the thoughts which are revealed in analysis were already active during the process of forming the dream; for, after working through a string of thoughts which seem to have no connection with the formation of a dream, one suddenly comes upon one which is represented in its content and is indispensable for its interpretation, but which could not have been reached except by this particular line of approach. I may here recall the dream of the botanical monograph, which strikes one as the product of an astonishing amount of condensation, even though I have not reported its analysis in full.

How, then, are we to picture psychical conditions during the period of sleep which precedes dreams? Are all the dream-thoughts present alongside one another? or do they occur in sequence? or do a number of trains of thought start out simultaneously from different centres and afterwards unite? There is no need for the present, in my opinion, to form any plastic idea of psychical conditions during the formation of dreams. It must not be forgotten, however, that we are dealing with an *unconscious* process of thought, which may easily be different from what we perceive during purposive reflection accompanied by consciousness.

The unquestionable fact remains, however, that the formation of dreams is based on a process of condensation. How is that condensation brought about?

When we reflect that only a small minority of all the dream-thoughts revealed are represented in the dream by one of their ideational elements, we might conclude that condensation is brought about by *omission*: that is, that the dream is not a faithful translation or a point-for-point projection of the dream thoughts, but a highly incomplete and fragmentary version of them. This view, as we shall soon discover, is a most inadequate one. But we may take it as a provisional starting-point and go on to a further question. If only a few elements from the dream-thoughts find their way into the dream-content, what are the conditions which determine their selection?

In order to get some light on this question we must turn our attention to those elements of the dream-content which must have fulfilled these conditions. And the most favourable material for such an investigation will be a dream to the construction of which a particularly intense process of condensation has contributed. I shall accordingly begin by choosing for the purpose the dream which I have already recorded on p. 657 ff.

I

THE DREAM OF THE BOTANICAL MONOGRAPH

CONTENT OF THE DREAM. - *I had written a monograph on an (unspecified) genus of plants. The book lay before me and I was at the moment turning over a folded coloured plate. Bound up in the copy there was a dried specimen of the plant.*

The element in this dream which stood out most was the *botanical monograph*. This arose from the impressions of the dream day: I had in fact seen a monograph on the genus *Cyclamen* in the window of a book-shop. There was no mention of this genus in the content of the dream; all that was left in it was the monograph and its relation to botany. The 'botanical monograph' immediately revealed its connection with the *work upon cocaine* which I had once written. From 'cocaine' the chains of thought led on the one hand to the *Festschrift* and to certain events in a University laboratory, and on the other hand to my friend Dr. Königstein, the eye surgeon, who had had a share in the introduction of cocaine. The figure of Dr. Königstein further reminded me of the interrupted conversation which I had had with him the evening before and of my various reflections upon the payment for medical services among colleagues. This conversation was the actual currently active instigator of the dream; the monograph on the cyclamen was also a currently active impression, but one of an indifferent nature. As I perceived, the 'botanical monograph' in the dream turned out to be an 'intermediate common entity' between the two experiences of the previous day: it was taken over unaltered from the indifferent impression and was linked with the psychically significant event by copious associative connections.

Not only the compound idea, 'botanical monograph', however, but each of its components, 'botanical' and 'monograph' separately, led by numerous connecting paths deeper and deeper into the tangle of dream-thoughts. 'Botanical' was related to the figure of Professor *Gärtner* [Gardener], the *blooming* looks of his wife, to my patient *Flora* and to the lady of whom I had told the story of the forgotten *flowers*. Gärtner led in turn to the laboratory and to my conversation with Königstein. My two patients had been mentioned in the course of this conversation. A train of thought joined the lady with the flowers to my wife's *favourite flowers* and thence to the title of the monograph which I had seen for a moment during the day. In addition to these, 'botanical' recalled an episode at my secondary school and an examination while I was at the University. A fresh topic touched upon in my conversation with Dr. Königstein - my *favourite* hobbies - was joined, through the intermediate link of what I jokingly called my *favourite flower*, the artichoke, with the train of thought proceeding from the forgotten flowers. Behind 'artichokes' lay, on the one hand, my thoughts about Italy and, on the other hand, a scene from my childhood which was the opening of what have since become my intimate relations with books. Thus 'botanical' was a regular nodal point in the dream. Numerous trains of thought converged upon it, which, as I can guarantee, had appropriately entered into the context of the conversation with Dr. Königstein. Here we find ourselves in a factory of thoughts where, as in the 'weaver's masterpiece' -

Ein Tritt tausend Fäden regt,
Die Schifflin herüber hinüber schiessen,
Die Fäden ungesehen fließen,
Ein Schlag tausend Verbindungen schlägt.¹

So, too, 'monograph' in the dream touches upon two subjects: the one-sidedness of my studies and the costliness of my favourite hobbies.

This first investigation leads us to conclude that the elements 'botanical' and 'monograph' found their way into the content of the dream because they possessed copious contacts with the majority of the dream-thoughts, because, that is to say, they constituted 'nodal points' upon which a great number of the dream-thoughts converged, and because they had several meanings in connection with the interpretation of the dream. The explanation of this fundamental fact can also be put in another way: each of the elements of the dream's content turns out to have been 'overdetermined' - to have been represented in the dream-thoughts many times over.

¹ [. . . a thousand threads one treadle throws,
Where fly the shuttles hither and thither,
Unseen the threads are knit together,
And an infinite combination grows.]

We discover still more when we come to examine the remaining constituents of the dream in relation to their appearance in the dream-thoughts. The *coloured plate* which I was unfolding led (see the analysis, p. 660 f.) to a new topic, my colleagues' criticisms of my activities, and to one which was already represented in the dream, my favourite hobbies; and it led, in addition, to the childhood memory in which I was pulling to pieces a book with coloured plates. The *dried specimen of the plant* touched upon the episode of the herbarium at my secondary school and specially stressed that memory.

The nature of the relation between dream-content and dream thoughts thus becomes visible. Not only are the elements of a dream determined by the dream-thoughts many times over, but the individual dream-thoughts are represented in the dream by several elements. Associative paths lead from one element of the dream to several dream-thoughts, and from one dream thought to several elements of the dream. Thus a dream is not constructed by each individual dream-thought, or group of dream-thoughts, finding (in abbreviated form) separate representation in the content of the dream - in the kind of way in which an electorate chooses parliamentary representatives; a dream is constructed, rather, by the whole mass of dream-thoughts being submitted to a sort of manipulative process in which those elements which have the most numerous and strongest supports acquire the right of entry into the dream-content - in a manner analogous to election by *scrutin de liste*. In the case of every dream which I have submitted to an analysis of this kind I have invariably found these same fundamental principles confirmed: the elements of the dream are constructed out of the whole mass of dream-thoughts and each one of those elements is shown to have been determined many times over in relation to the dream-thoughts.

It will certainly not be out of place to illustrate the connection between dream-content and dream-thoughts by a further example, which is distinguished by the specially ingenious interweaving of their reciprocal relations. It is a dream produced by one of my patients - a man whom I was treating for claustrophobia. It will soon become clear why I have chosen to give this exceptionally clever dream-production the title of

II

'A LOVELY DREAM'

He was driving with a large party to X Street, in which there was an unpretentious inn. (This is not the case.) There was a play being acted inside it. At one moment he was audience, at another actor. When it was over, they had to change their clothes so as to get back to town. Some of the company were shown into rooms on the ground floor and others into rooms on the first floor. Then a dispute broke out. The ones up above were angry because the ones down below were not ready, and they could not come downstairs. His brother was up above and he was down below and he was angry with his brother because they were so much pressed. (This part was obscure.) Moreover it had been decided and arranged even when they first arrived who was to be up above and who was to be down below. Then he was walking by himself up the rise made by X Street in the direction of town. He walked with such difficulty and so laboriously that he seemed glued to the spot. An elderly gentleman came up to him and began abusing the King of Italy. At the top of the rise he was able to walk much more easily.

His difficulty in walking up the rise was so distinct that after waking up he was for some time in doubt whether it was a dream or reality.

We should not think very highly of this dream, judging by its manifest content. In defiance of the rules, I shall begin its interpretation with the portion which the dreamer described as being the most distinct.

The difficulty which he dreamt of and probably actually experienced during the dream - the laborious climbing up the rise accompanied by dyspnoea - was one of the symptoms which the patient had in fact exhibited years before and which had at that time been attributed, along with certain other symptoms, to tuberculosis. (The probability is that this was hysterically simulated.) The peculiar sensation of inhibited movement that occurs in this dream is already familiar to us from dreams of exhibiting and we see once more that it is material available at any time for any other representational purpose. The piece of the dream-content which described how the climb began by being difficult and became easy at the end of the rise reminded me, when I heard it, of the masterly introduction to Alphonse Daudet's *Sappho*. That well known passage describes how a young man carries his mistress upstairs in his arms; at first she is as light as a feather, but the higher he climbs the heavier grows her weight. The whole scene foreshadows the course of their love-affair, which was intended by Daudet as a warning to young men not to allow their affections to be seriously engaged by girls of humble origin and a dubious past.¹ Though I knew that my patient had been involved in a love-affair which he had recently broken off with a lady on the stage, I did not expect to find my guess at an interpretation justified. Moreover the situation in *Sappho* was the *reverse* of what it had been in the dream. In the dream the climbing had been difficult to begin with and had afterwards become easy; whereas the symbolism in the novel only made sense if something that had been begun lightly ended by becoming a heavy burden. But to my astonishment my patient replied that my interpretation fitted in very well with a piece he had seen at the theatre the evening before. It was called *Rund um Wien* [*Round Vienna*] and gave a picture of the career of a girl who began by being respectable, who then became a *demi-mondaine* and had *liaisons* with men in high positions and so '*went up in the world*', but who ended by '*coming down in the world*.' The piece had moreover reminded him of another, which he had seen some years earlier, called *Von Stufe zu Stufe* [*Step by Step*], and which had been advertised by a poster showing a staircase with a flight of *steps*.

To continue with the interpretation. The actress with whom he had had this latest, eventful *liaison* had lived in X Street. There is nothing in the nature of an inn in that street. But when he was spending part of the summer in Vienna on the lady's account he had put up at a small hotel in the neighbourhood. When he left the hotel he had said to his cab-driver: 'Anyhow I'm lucky not to have picked up any vermin.' (This, incidentally, was another of his phobias.) To this the driver had replied: 'How could any one put up at such a place! It's not a hotel, it's only an *inn*.'

¹ [Footnote added 1911:] What I have written below in the section on symbolism about the significance of dreams of climbing throws light upon the imagery chosen by the novelist.

The idea of an inn at once recalled a quotation to his mind:

Bei einem *Wirte* wundermild,
Da war ich jüngst zu Gaste.¹

The host in Uhland's poem was an *apple tree*; and a second quotation now carried on his train of thought:

FAUST (*mit der Jugend tanzend*):

Einst hatt' ich *einen schönen Traum*;
Da sah ich einen *Apfelbaum*,
Zwei schöne Äpfel glänzten dran,
Sie reizten mich, *ich stieg hinan*.

DIE SCHÖNE:

Der Äpfelchen begehrt ihr sehr,
Und schon vom Paradiese her.
Von Freuden fühl' ich mich bewegt,
Dass auch mein Garten solche trägt.²

There cannot be the faintest doubt what the apple-tree and the apples stood for. Moreover, lovely breasts had been among the charms which had attracted the dreamer to his actress.

The context of the analysis gave us every ground for supposing that the dream went back to an impression in childhood. If so, it must have referred to the wet-nurse of the dreamer, who was by now a man almost thirty years old. For an infant the breasts of his wet-nurse are nothing more nor less than an inn. The wet-nurse, as well as Daudet's Sappho, seem to have been allusions to the mistress whom the patient had recently dropped.

The patient's (elder) brother also appeared in the content of the dream, the brother being *up above* and the patient himself *down below*. This was once again the *reverse* of the actual situation; for, as I knew, the brother had lost his social position while the patient had maintained his. In repeating the content of the dream to me, the dreamer had avoided saying that his brother was up above and he himself 'on the ground floor'. That would have put the position too clearly, since here in Vienna if we say someone is '*on the ground floor*' we mean that he has lost his money and his position - in other words, that he has '*come down in the world*'. Now there must have been a reason for some of this part of the dream being represented by its *reverse*. Further, the reversal must hold good of some other relation between dream-thoughts and dream-content as well; and we have a hint of where to look for this reversal. It must evidently be at the end of the dream, where once again there was a *reversal* of the difficulty in going upstairs as described in *Sappho*. We can then easily see what reversal is intended. In *Sappho* the man carried a woman who was in a sexual relation to him; in the dream-thoughts the position was *reversed*, and a woman was carrying a man. And since this can only happen in childhood, the reference was once more to the wet-nurse bearing the weight of the infant in her arms. Thus the end of the dream made a simultaneous reference to Sappho and to the wet-nurse.

¹ [Literally: 'I was lately a guest at an *inn* with a most gentle host.']

² [FAUST (*dancing with the Young Witch*):

A *lovely dream* once came to me,
And I beheld an *apple-tree*,
On which two lovely apples shone;
They charmed me so, *I climbed thereon*.

THE LOVELY WITCH:

Apples have been desired by you,
Since first in Paradise they grew;
And I am moved with joy to know
That much within my garden grow.]

Just as the author of the novel, in choosing the name 'Sappho', had in mind an allusion to Lesbian practices, so too the pieces of the dream that spoke of people '*up above*' and '*down below*' alluded to phantasies of a sexual nature which occupied the patient's mind and, as suppressed desires, were not without a bearing on his neurosis. (The interpretation of the dream did not itself show us that what were thus represented in the dream were phantasies and not recollections of real events; an analysis only gives us the *content* of a thought and leaves it to us to determine its reality. Real and imaginary events appear in dreams at first sight as of equal validity; and that is so not only in dreams but in the production of more important psychical structures.)

A 'large party' meant, as we already know, a secret. His brother was simply the representative (introduced into the childhood scene by a 'retrospective phantasy') of all his later rivals for a woman's affection. The episode of the gentleman who abused the King of Italy related once again, *via* the medium of a recent and in itself indifferent experience, to people of lower rank pushing their way into higher society. It was just as though the child at the breast was being given a warning parallel to the one which Daudet had given to young men.¹

¹ The imaginary nature of the situation relating to the dreamer's wet-nurse was proved by the objectively established fact that in his case the wet-nurse had been his mother. I may recall in this connection the anecdote, which I repeated on p. 688, of the young man who regretted that he had not made better use of his opportunities with his wet-nurse. A regret of the same kind was no doubt the source of the present dream.

To provide a third opportunity for studying condensation in the formation of dreams, I will give part of the analysis of another dream, which I owe to an elderly lady undergoing psycho-analytic treatment. As was to be expected from the severe anxiety-states from which the patient suffered, her dreams contained a very large number of sexual thoughts, the first realization of which both surprised and alarmed her. Since I shall not be able to pursue the interpretation of the dream to the end, its material will appear to fall into several groups without any visible connection.

III

'THE MAY-BEETLE DREAM'

CONTENT OF THE DREAM. - *She called to mind that she had two may-beetles in a box and that she must set them free or they would suffocate. She opened the box and the may-beetles were in an exhausted state. One of them flew out of the open window; but the other was crushed by the casement while she was shutting it at someone's request. (Signs of disgust.)*

ANALYSIS. - Her husband was temporarily away from home, and her fourteen-year-old daughter was sleeping in the bed beside her. The evening before, the girl had drawn her attention to a moth which had fallen into her tumbler of water; but she had not taken it out and felt sorry for the poor creature next morning. The book she had been reading during the evening had told how some boys had thrown a cat into boiling water, and had described the animal's convulsions. These were the two precipitating causes of the dream - in themselves indifferent. She then pursued the subject of *cruelty to animals* further. Some years before, while they were spending the summer at a particular place, her daughter had been very cruel to animals. She was collecting butterflies and asked the patient for some *arsenic* to kill them with. On one occasion a moth with a pin through its body had gone on flying about the room for a long time; another time some caterpillars which the child was keeping to turn into chrysalises starved to death. At a still more tender age the same child used to tear the wings off *beetles* and butterflies. But to-day she would be horrified at all these cruel actions she had grown so kind-hearted.

The patient reflected over this contradiction. It reminded her of another contradiction, between appearance and character, as George Eliot displays it in *Adam Bede*: one girl who was pretty, but vain and stupid, and another who was ugly, but of high character; a nobleman who seduced the silly girl, and a working man who felt and acted with true nobility. How impossible it was, she remarked, to recognize that sort of thing in people! Who would have guessed, to look at *her*, that she was tormented by sensual desires?

In the same year in which the little girl had begun collecting butterflies, the district they were in had suffered from a serious plague of *may-beetles*. The children were furious with the beetles and *crushed* them unmercifully. At that time my patient had seen a man who tore the wings off may-beetles and then ate their bodies. She herself had been born in *May* and had been married in *May*. Three days after her marriage she had written to her parents at home saying how happy she was. But it had been far from true.

The evening before the dream she had been rummaging among some old letters and had read some of them - some serious and some comic - aloud to her children. There had been a most amusing letter from a piano-teacher who had courted her when she was a girl, and another from an admirer of *noble birth*.¹

¹ This had been the true instigator of the dream.

She blamed herself because one of her daughters had got hold of a 'bad' book by Maupassant.¹ The *arsenic* that the girl had asked for reminded her of the *arsenic pills* which restored the Duc de Mora's youthful strength in *Le Nabab*.

'Set them free' made her think of a passage in the *Magic Flute*:

Zur Liebe kann ich dich nicht zwingen,
Doch geb ich dir *die Freiheit* nicht.²

'May-beetles' also made her think of Kätchen's words:

Verliebt ja wie ein *Käfer* bist du mir.³

And in the middle of all this came a quotation from *Tannhäuser*:

Weil du von *böser* Lust beseelt . . .⁴

She was living in a perpetual worry about her absent husband. Her fear that something might happen to him on his journey was expressed in numerous waking phantasies. A short time before, in the course of her analysis, she had lighted among her unconscious thoughts upon a complaint about her husband 'growing senile'. The wishful thought concealed by her present dream will perhaps best be conjectured if I mention that, some days before she dreamt it, she was horrified, in the middle of her daily affairs, by a phrase in the imperative mood which came into her head and was aimed at her husband: 'Go and hang yourself!' It turned out that a few hours earlier she had read somewhere or other that when a man is hanged he gets a powerful erection. The wish for an erection was what had emerged from repression in this horrifying disguise. 'Go and hang yourself!' was equivalent to: 'Get yourself an erection at any price!' Dr. Jenkins's arsenic pills in *Le Nabab* fitted in here. But my patient was also aware that the most powerful aphrodisiac, cantharides (commonly known as 'Spanish flies'), was prepared from *crushed beetles*. This was the drift of the principal part of the dream's content.

The opening and shutting of *windows* was one of the main subjects of dispute between her and her husband. She herself was aerophilic in her sleeping habits; her husband was aerophobic. *Exhaustion* was the chief symptom which she complained of at the time of the dream.

¹ An interpolation is required at this point: 'books of that kind are *poison* to a girl.' The patient herself had dipped into forbidden books a great deal when she was young.

² [Fear not, to love I'll ne'er compel thee;
Yet 'tis too soon to *set thee free*.]

³ ['You are madly in love with me.' Literally: 'You are in love with me like a *beetle*.'] - A further train of thought led to the same poet's *Penthesilia*, and to the idea of *cruelty* to a lover.

⁴ [Literally: 'Because thou wast inspired by such *evil pleasure*.']

In all three of the dreams which I have just recorded, I have indicated by italics the points at which one of the elements of the dream-content reappears in the dream-thoughts, so as to show clearly the multiplicity of connections arising from the former. Since, however, the analysis of none of these dreams has been traced to its end, it will perhaps be worth while to consider a dream whose analysis has been recorded exhaustively, so as to show how its content is over-determined. For this purpose I will take the dream of Irma's injection. It will be easy to see from that example that the work of condensation makes use of more than one method in the construction of dreams.

The principal figure in the dream-content was my patient Irma. She appeared with the features which were hers in real life, and thus, in the first instance, represented herself. But the position in which I examined her by the window was derived from someone else, the lady for whom, as the dream-thoughts showed, I wanted to exchange my patient. In so far as Irma appeared to have a diphtheritic membrane, which recalled my anxiety about my eldest daughter, she stood for that child and, behind her, through her possession of the same name as my daughter, was hidden the figure of my patient who succumbed to poisoning. In the further course of the dream the figure of Irma acquired still other meanings, without any alteration occurring in the visual picture of her in the dream. She turned into one of the children whom we had examined in the neurological department of the children's hospital, where my two friends revealed their contrasting characters. The figure of my own child was evidently the stepping-stone towards this transition. The same 'Irma's' recalcitrance over opening her mouth brought an allusion to another lady whom I had once examined, and, through the same connection, to my wife. Moreover, the pathological changes which I discovered in her throat involved allusions to a whole series of other figures.

None of these figures whom I lighted upon by following up 'Irma' appeared in the dream in bodily shape. They were concealed behind the dream figure of 'Irma', which was thus turned into a collective image with, it must be admitted, a number of contradictory characteristics. Irma became the representative of all these other figures which had been sacrificed to the work of condensation, since I passed over to *her*, point by point, everything that reminded me of *them*.

There is another way in which a 'collective figure' can be produced for purposes of dream-condensation, namely by uniting the actual features of two or more people into a single dream-image. It was in this way that the Dr. M. of my dream was constructed. He bore the name of Dr. M., he spoke and acted like him; but his physical characteristics and his malady belonged to someone else, namely to my eldest brother. One single feature, his pale appearance, was doubly determined, since it was common to both of them in real life.

Dr. R. in my dream about my uncle with the yellow beard was a similar composite figure. But in his case the dream-image was constructed in yet another way. I did not combine the features of one person with those of another and in the process omit from the memory-picture certain features of each of them. What I did was to adopt the procedure by means of which Galton produced family by portraits: namely by projecting two images on to a single plate, so that certain features common to both are emphasized, while those which fail to fit in with one another cancel one another out and are indistinct in the picture. In my dream about my uncle the fair beard emerged prominently from a face which belonged to two people and which was consequently blurred; incidentally, the beard further involved an allusion to my father and myself through the intermediate idea of growing grey.

The construction of collective and composite figures is one of the chief methods by which condensation operates in dreams. I shall presently have occasion to deal with them in another context.

The occurrence of the idea of 'dysentery' in the dream of Irma's injection also had a multiple determination: first owing to its phonetic similarity to 'diphtheria', and secondly owing to its connection with the patient whom I had sent to the East and whose hysteria was not recognized.

Another interesting example of condensation in this dream was the mention in it of 'propyls'. What was contained in the dream-thoughts was not 'propyls' but 'amyls.' It might be supposed that a single displacement had taken place at this point in the construction of the dream. This was indeed the case. But the displacement served the purposes of condensation, as is proved by the following addition to the analysis of the dream. When I allowed my attention to dwell for a moment longer on the word 'propyls', it occurred to me that it sounded like 'Propylaea'. But there are Propylaea not only in Athens but in Munich. A year before the dream I had gone to Munich to visit a friend who was seriously ill at the time - the same friend who was unmistakably alluded to in the dream by the word 'trimethylamin' which occurred immediately after 'propyls.'

I shall pass over the striking way in which here, as elsewhere in dream-analyses, associations of the most various inherent importance are used for laying down thought-connections as though they were of equal weight, and shall yield to the temptation to give, as it were, a plastic picture of the process by which the amyls in the dream-thoughts were replaced by propyls in the dream-content.

On the one hand we see the group of ideas attached to my friend Otto, who did not understand me, who sided against me, and who made me a present of liqueur with an aroma of amyl. On the other hand we see - linked to the former group by its very contrast - the group of ideas attached to my friend in Berlin, who *did* understand me, who would take my side, and to whom I owed so much valuable information, dealing, amongst other things, with the chemistry of the sexual processes.

The recent exciting causes - the actual instigators of the dream - determined what was to attract my attention in the 'Otto' group; the amyl was among these selected elements, which were predestined to form part of the dream-content. The copious 'Wilhelm' group was stirred up precisely through being in contrast to 'Otto', and those elements in it were emphasized which echoed those which were already stirred up in 'Otto'. All though the dream, indeed, I kept on turning from someone who annoyed me to someone else who could be agreeably contrasted with him; point by point, I called up a friend against an opponent. Thus the amyl in the 'Otto' group produced memories from the field of chemistry in the other group; in this manner the trimethylamin, which was supported from several directions, found its way into the dream-content. 'Amyls' itself might have entered the dream-content unmodified; but it came under the influence of the 'Wilhelm' group. For the whole range of memories covered by that name was searched through in order to find some element which could provide a two-sided determination for 'amyls.' 'Propyls' was closely associated with 'amyls', and Munich from the 'Wilhelm' group with its 'propylaea' came half-way to meet it. The two groups of ideas converged in 'propyls-propylaea'; and, as though by an act of compromise, this intermediate element was what found its way into the dream-content. Here an intermediate common entity had been constructed which admitted of multiple determination. It is obvious, therefore, that multiple determination must make it easier for an element to force its way into the dream-content. In order to construct an intermediate link of this kind, attention is without hesitation displaced from what is actually intended on to some neighbouring association.

Our study of the dream of Irma's injection has already enabled us to gain some insight into the processes of condensation during the formation of dreams. We have been able to observe certain of their details, such as how preference is given to elements that occur several times over in the dream-thoughts, how new unities are formed (in the shape of collective figures and composite structures), and how intermediate common entities are constructed. The further questions of the *purpose* of condensation and of the factors which tend to produce it will not be raised till we come to consider the whole question of the psychical processes at work in the formation of dreams. We will be content for the present with recognizing the fact that dream-condensation is a notable characteristic of the relation between dream-thoughts and dream-content.

The work of condensation in dreams is seen at its clearest when it handles words and names. It is true in general that words are frequently treated in dreams as though they were things, and for that reason they are apt to be combined in just the same way as are presentations of things. Dreams of this sort offer the most amusing and curious neologisms.

I

On one occasion a medical colleague had sent me a paper he had written, in which the importance of a recent physiological discovery was, in my opinion, overestimated, and in which, above all, the subject was treated in too emotional a manner. The next night I dreamt a sentence which clearly referred to this paper: '*Its written in a positively norekdal style.*' The analysis of the word caused me some difficulty at first. There could be no doubt that it was a parody of the superlatives '*kolossal*' and '*pyramidal*'; but its origin was not so easy to guess. At last I saw that the monstrosity was composed of the two names 'Nora' and 'Ekdal' - characters in two well-known plays of Ibsen's. Some time before, I had read a newspaper article on Ibsen by the same author whose latest work I was criticizing in the dream.

II

One of my women patients told me a short dream which ended in a meaningless verbal compound. She dreamt she was with her husband at a peasant festivity and said: '*This will end in a general "Maistollmütz."*' In the dream she had a vague feeling that it was some kind of pudding made with maize - a sort of polenta. Analysis divided the word into '*Mais*' ['maize'], '*toll*' ['mad'], '*mannstoll*' ['nymphomaniac' - literally 'mad for men'] and '*Olmütz*' [a town in Moravia]. All these fragments were found to be remnants of a conversation she had had at table with her relatives. The following words lay behind '*Mais*' (in addition to a reference to the recently opened Jubilee Exhibition): '*Meissen*' (a Meissen porcelain figure representing a bird); '*Miss*' (her relatives' English governess had just gone to *Olmütz*); and '*mies*' (a Jewish slang term, used jokingly to mean 'disgusting'). A long chain of thoughts and associations led off from each syllable of this verbal hotch potch.

III

A young man, whose door-bell had been rung late one night by an acquaintance who wanted to leave a visiting-card on him, had a dream that night: *A man had been working till late in the evening to put his house-telephone in order. After he had gone, it kept on ringing - not continuously, but with detached rings. His servant fetched the man back, and the latter remarked: 'It's a funny thing that even people who are "tutelrein" as a rule are quite unable to deal with a thing like this.'*

It will be seen that the indifferent exciting cause of the dream only covers one element of it. That episode only obtained any importance from the fact that the dreamer put it in the same series as an earlier experience which, though equally indifferent in itself, was given a substitutive meaning by his imagination. When he was a boy, living with his father, he had upset a glass of water over the floor while he was half-asleep. The flex of the house-telephone had been soaked through and its *continuous ringing* had disturbed his father's sleep. Since the continuous ringing corresponded to getting wet, the '*detached rings*' were used to represent drops falling. The word '*tutelrein*' could be analysed in three directions, and led in that way to three of the subjects represented in the dream-thoughts. '*Tutel*' is a legal term for 'guardianship' ['tutelage']. '*Tutel*' (or possibly '*Tuttel*') is also a vulgar term for a woman's breast. The remaining portion of the word, '*rein*' ['clean'], combined with the first part of '*Zimmertelegraph*' ['house-telephone'], forms '*zimmerrein*' ['house-trained'] - which is closely connected with making the floor wet, and, in addition, sounded very much like the name of a member of the dreamer's family.¹

¹ In waking life this same kind of analysis and synthesis of syllables - a syllabic chemistry, in fact - plays a part in a great number of jokes: 'What is the cheapest way of obtaining silver? You go down an avenue of silver poplars [*Pappel*], which means both "poplars" and "babbling"] and call for silence. The babbling then ceases and the silver is released.' The first reader and critic of this book - and his successors are likely to follow his example - protested that 'the dreamer seems to be too ingenious and amusing.' This is quite true so long as it refers only to the dreamer; it would only be an objection if it were to be extended to the dream-interpreter. In waking reality I have little claim to be regarded as a wit. If my dreams seem amusing, that is not on my account, but on account of the peculiar psychological conditions under which dreams are constructed; and the fact is intimately connected with the theory of jokes and the comic. Dreams become ingenious and amusing because the direct and easiest pathway to the expression of their thoughts is barred: they are forced into being so. The reader can convince himself that my patients' dreams seem at least as full of jokes and puns as my own, or even fuller. - [Added 1909:] Nevertheless this objection led me to compare the technique of jokes with the dream-work; and the results are to be found in the book which I published on Jokes and their Relation to the Unconscious (1905c).

IV

In a confused dream of my own of some length, whose central point seemed to be a sea voyage, it appeared that the next stopping place was called '*Hearsing*' and the next after that '*Fliess*.' This last word was the name of my friend, who has often been the goal of my travels. 'Hearsing' was a compound. One part of it was derived from the names of places on the suburban railway near Vienna, which so often end in 'ing': Hietzing, Liesing, Mödling (Medelitz, '*meae deliciae*', was its old name - that is '*meine Freud*' ['my delight']). The other part was derived from the English word 'hearsay.' This suggested slander and established the dream's connection with its indifferent instigator of the previous day: a poem in the periodical *Fliegende Blätter* about a slanderous dwarf called 'Sagter Hatergesagt' ['He-says Says-he']. If the syllable 'ing' were to be added to the name 'Fliess' we should get 'Vlissingen', which was in fact the stopping-place on the sea voyage made by my brother whenever he visited us from England. But the English name for Vlissingen is 'Flushing', which in English means 'blushing' and reminded me of the patients I have treated for ereutophobia, and also of a recent paper on that neurosis by Bechterew which had caused me some annoyance.

V

On another occasion I had a dream which consisted of two separate pieces. The first piece was the word 'Autodidasker', which I recalled vividly. The second piece was an exact reproduction of a short and harmless phantasy which I had produced some days before. This phantasy was to the effect that when I next saw Professor N. I must say to him: 'The patient about whose condition I consulted you recently is in fact only suffering from a neurosis, just as you suspected.' Thus the neologism 'Autodidasker' must satisfy two conditions: firstly, it must bear or represent a composite meaning; and secondly, that meaning must be solidly related to the intention I had reproduced from waking life of making amends to Professor N.

The word 'Autodidasker' could easily be analysed into 'Autor' [author], 'Autodidakt' [self-taught] and 'Lasker', with which I also associated the name of Lassalle. The first of these words led to the precipitating cause of the dream - this time a significant one. I had given my wife several volumes by a well-known writer who was a friend of my brother's, and who, as I have learnt, was a native of my own birthplace: J. J. David. One evening she had told me of the deep impression that had been made on her by the tragic story in one of David's books of how a man of talent went to the bad; and our conversation had turned to a discussion of the gifts of which we saw signs in our own children. Under the impact of what she had been reading, my wife expressed concern about the children, and I consoled her with the remark that those were the very dangers which could be kept at bay by a good upbringing. My train of thought was carried further during the night; I took up my wife's concern and wove all kinds of other things into it. A remark made by the author to my brother on the subject of marriage showed my thoughts a by-path along which they might come to be represented in the dream. This path led to Breslau, where a lady with whom we were very friendly had gone to be married and settle down. The concern I felt over the danger of coming to grief over a woman - for that was the kernel of my dream-thoughts - found an example in Breslau in the cases of Lasker and Lassalle which made it possible to give a simultaneous picture of the two ways in which this fatal influence can be exercised. '*Cherchez la femme*', the phrase in which these thoughts could be summarized, led me, taken in another sense, to my still unmarried brother, whose name is Alexander. I now perceived that 'Alex', the shortened form of the name by which we call him, has almost the same sound as an anagram of 'Lasker', and that this factor must have had a share in leading my thoughts along the by-path by way of Breslau.

¹ Lasker died of tabes, that is, as a result of an infection (syphilis) contracted from a woman; Lassalle, as everyone knows, fell in a duel on account of a woman.

The play which I was making here upon names and syllables had a still further sense, however. It expressed a wish that my brother might have a happy domestic life, and it did so in this way. In Zola's novel of an artist's life, *L'oeuvre*, the subject of which must have been close to my dream-thoughts, its author, as is well known, introduced himself and his own domestic happiness as an episode. He appears under the name of 'Sandoz.' The transformation was probably arrived at as follows. If 'Zola' is written backwards (the sort of thing children are so fond of doing), we arrive at 'Aloz.' No doubt this seemed too undisguised. He therefore replaced 'Al', which is the first syllable of 'Alexander' by 'Sand', which is the third syllable of the same name; and in this way 'Sandoz' came into being. My own 'Autodidasker' arose in much the same fashion.

I must now explain how my phantasy of telling Professor N. that the patient we had both examined was only suffering from a neurosis made its way into the dream. Shortly before the end of my working year, I began the treatment of a new patient who quite baffled my powers of diagnosis. The presence of a grave organic disease - perhaps some degeneration of the spinal cord - strongly suggested itself but could not be established. It would have been tempting to diagnose a neurosis (which would have solved every difficulty), if only the patient had not repudiated with so much energy the sexual history without which I refuse to recognize the presence of a neurosis. In my embarrassment I sought help from the physician whom I, like many other people, respect more than any as a man and before whose authority I am readiest to bow. He listened to my doubts, told me they were justified, and then gave his opinion: 'Keep the man under observation; it must be a neurosis.' Since I knew he did not share my views on the aetiology of the neuroses, I did not produce my counter-argument, but I made no concealment of my scepticism. A few days later I informed the patient that I could do nothing for him and recommended him to seek other advice. Whereupon, to my intense astonishment, he started apologizing for having lied to me. He had been too much ashamed of himself, he said, and went on to reveal precisely the piece of sexual aetiology which I had been expecting and without which I had been unable to accept his illness as a neurosis. I was relieved but at the same time humiliated. I had to admit that my consultant, not being led astray by considering the anamnesis, had seen more clearly than I had. And I proposed to tell him as much when I next met him - to tell him that *he* had been right and *I* wrong.

This was precisely what I did in the dream. But what sort of a wish-fulfilment can there have been in confessing that I was wrong?. To be wrong was, however, just what I *did* wish. I wanted to be wrong in my fears, or, more precisely, I wanted my wife, whose fears I had adopted in the dream-thoughts, to be wrong. The subject round which the question of right or wrong revolved in the dream was not far removed from what the dream-thoughts were really concerned with. There was the same alternative between organic and functional damage caused by a woman, or, more properly, by sexuality: tabetic paralysis or neurosis? (The manner of Lassalle's death could be loosely classed in the latter category.)

In this closely knit and, when it was carefully interpreted, very transparent dream, Professor N. played a part not only on account of this analogy and of my wish to be wrong, and on account of his incidental connections with Breslau and with the family of our friend who had settled there after her marriage but also on account of the following episode which occurred at the end of our consultation. When he had given his opinion and so concluded our medical discussion, he turned to more personal subjects: 'How many children have you got now?' - 'Six.' - He made a gesture of admiration and concern. - 'Girls or boys?' - 'Three and three: they are my pride and my treasure.' - 'Well, now, be on your guard! Girls are safe enough, but bringing up boys leads to difficulties later on.' - I protested that mine had been very well behaved so far. Evidently this second diagnosis, on the future of my boys, pleased me no more than the earlier one, according to which my patient was suffering from a neurosis. Thus these two impressions were bound up together by their contiguity, by the fact of their having been experienced both at once; and in taking the story of the neurosis into my dream, I was substituting it for the conversation about upbringing, which had more connection with the dream-thoughts, since it touched so closely upon the worries later expressed by my wife. So even my fear that N. might be right in what he said about the difficulty of bringing up boys had found a place in the dream, for it lay concealed behind the representation of my wish that I myself might be wrong in harbouring such fears. The same phantasy served unaltered to represent both of the opposing alternatives.

VI

'Early this morning,¹ between dreaming and waking, I experienced a very nice example of verbal condensation. In the course of a mass of dream-fragments that I could scarcely remember, I was brought up short, as it were, by a word which I saw before me as though it were half written and half printed. The word was "*erzefilisch*", and it formed part of a sentence which slipped into my conscious memory apart from any context and in complete isolation: "That has an *erzefilisch* influence on the sexual emotions." I knew at once that the word ought really to have been "*erzieherisch*" ["educational"]. And I was in doubt for some time whether the second "e" in "*erzefilisch*" should not have been an "i". In that connection the word "syphilis" occurred to me and, starting to analyse the dream while I was still half asleep, I racked my brains in an effort to make out how that word could have got into my dream, since I had nothing to do with the disease either personally or professionally. I then thought of "*erzehlerisch*" [another nonsense word], and this explained the "e" of the second syllable of "*erzefilisch*" by reminding me that the evening before I had been asked by our governess [*Erzieherin*] to say something to her on the problem of prostitution, and had given her Hesse's book on prostitution in order to influence her emotional life - for this had not developed quite normally; after which I had talked [*erzählt*] a lot to her on the problem. I then saw all at once that the word "syphilis" was not to be taken literally, but stood for "poison" - of course in relation to sexual life. When translated, therefore, the sentence in the dream ran quite logically: "My talk [*Erzählung*] was intended to have an educational [*erzieherisch*] influence on the emotional life of our governess [*Erzieherin*]; but I fear it may at the same time have had a poisonous effect." "*Erzefilisch*" was compounded from "*erzäh-*" and "*erzieh-*".'

¹ Quoted from Marcinowski.

The verbal malformations in dreams greatly resemble those which are familiar in paranoia but which are also present in hysteria and obsessions. The linguistic tricks performed by children, who sometimes actually treat words as though they were objects and moreover invent new languages and artificial syntactic forms, are the common source of these things in dreams and psychoneuroses alike.

The analysis of the nonsensical verbal forms that occur in dreams is particularly well calculated to exhibit the dream work's achievements in the way of condensation. The reader should not conclude from the paucity of the instances which I have given that material of this kind is rare or observed at all exceptionally. On the contrary, it is very common. But as a result of the fact that dream-interpretation is dependent upon psycho-analytic treatment, only a very small number of instances are observed and recorded and the analyses of such instances are as a rule only intelligible to experts in the pathology of the neuroses. Thus a dream of this kind was reported by Dr. von Karpinska (1914) containing the nonsensical verbal form: '*Svingnum elvi*.' It is also worth mentioning those cases in which a word appears in a dream which is not in itself meaningless but which has lost its proper meaning and combines a number of other meanings to which it is related in just the same way as a 'meaningless' word would be. This is what occurred, for instance, in the ten-year-old boy's dream of a 'category' which was recorded by Tausk (1913). 'Category' in that case meant 'female genitals', and to 'categorate' meant the same as 'to micturate.'

Where spoken sentences occur in dreams and are expressly distinguished as such from thoughts, it is an invariable rule that the words spoken in the dream are derived from spoken words remembered in the dream-material. The text of the speech is either retained unaltered or expressed with some slight displacement. A speech in a dream is often put together from various recollected speeches, the text remaining the same but being given, if possible, several meanings, or one different from the original one. A spoken remark in a dream is not infrequently no more than an allusion to an occasion on which the remark in question was made.¹

¹ [*Footnote added 1909:*] Not long ago I found a single exception to this rule in the case of a young man who suffered from obsessions while retaining intact his highly developed intellectual powers. The spoken words which occurred in his dreams were not derived from remarks which he had heard or made himself. They contained the undistorted text of his obsessional thoughts, which in his waking life only reached his consciousness in a modified form.

(B)

THE WORK OF DISPLACEMENT

In making our collection of instances of condensation in dreams, the existence of another relation, probably of no less importance, had already become evident. It could be seen that the elements which stand out as the principal components of the manifest content of the dream are far from playing the same part in the dream-thoughts. And, as a corollary, the converse of this assertion can be affirmed: what is clearly the essence of the dream-thoughts need not be represented in the dream at all. The dream is, as it were, differently centred from the dream thoughts - its content has different elements as its central point. Thus in the dream of the botanical monograph, for instance, the central point of the dream-content was obviously the element 'botanical'; whereas the dream-thoughts were concerned with the complications and conflicts arising between colleagues from their professional obligations, and further with the charge that I was in the habit of sacrificing too much for the sake of my hobbies. The element 'botanical' had no place whatever in this core of the dream-thoughts, unless it was loosely connected with it by an antithesis - the fact that botany never had a place among my favourite studies. In my patient's *Sappho* dream the central position was occupied by climbing up and down and being up above and down below; the dream-thoughts, however, dealt with the dangers of sexual relations with people of an inferior social class. So that only a single element of the dream-thoughts seems to have found its way into the dream-content, though that element was expanded to a disproportionate extent. Similarly, in the dream of the may-beetles, the topic of which was the relations of sexuality to cruelty, it is true that the factor of cruelty emerged in the dream-content; but it did so in another connection and without any mention of sexuality, that is to say, divorced from its context and consequently transformed into something extraneous. Once again, in my dream about my uncle, the fair beard which formed its centre-point seems to have had no connection in its meaning with my ambitious wishes which, as we saw, were the core of the dream-thoughts. Dreams such as these give a justifiable impression of 'displacement.' In complete contrast to these examples, we can see that in the dream of Irma's injection the different elements were able to retain, during the process of constructing the dream, the approximate place which they occupied in the dream-thoughts. This further relation between the dream-thoughts and the dream-content, wholly variable as it is in its sense or direction, is calculated at first to create astonishment. If we are considering a psychical process in normal life and find that one out of its several component ideas has been picked out and has acquired a special degree of vividness in consciousness, we usually regard this effect as evidence that a specially high amount of psychical value - some particular degree of interest - attaches to this predominant idea. But we now discover that, in the case of the different elements of the dream-thoughts, a value of this kind does not persist or is disregarded in the process of dream-formation. There is never any doubt as to which of the elements of the dream-thoughts have the highest psychical value, we learn that by direct judgement. In the course of the formation of a dream these essential elements, charged, as they are, with intense interest, may be treated as though they were of small value, and their place may be taken in the dream by other elements, of whose small value in the dream-thoughts there can be no question. At first sight it looks as though no attention whatever is paid to the psychical intensity¹ of the various ideas in making the choice among them for the dream, and as though the only thing considered is the greater or less degree of multiplicity of their determination. What appears in dreams, we might suppose, is not what is important in the dream-thoughts but what occurs in them several times over. But this hypothesis does not greatly assist our understanding of dream-formation, since from the nature of things it seems clear that the two factors of multiple determination and inherent psychical value must necessarily operate in the same sense. The ideas which are most important among the dream-thoughts will almost certainly be those which occur most often in them, since the different dream-thoughts will, as it were, radiate out from them. Nevertheless a dream can reject elements which are thus both highly stressed in themselves and reinforced from many directions, and can select for its content other elements which possess only the second of these attributes.

¹ *Psychical* intensity or value or the degree of interest of an idea is of course to be distinguished from *sensory* intensity or the intensity of the image presented.

In order to solve this difficulty we shall make use of another impression derived from our enquiry into the overdetermination of the dream-content. Perhaps some of those who have read that enquiry may already have formed an independent conclusion that the overdetermination of the elements of dreams is no very important discovery, since it is a self-evident one. For in analysis we start out from the dream-elements and note down all the associations which lead off from them; so that there is nothing surprising in the fact that in the thought-material arrived at in this way we come across these same elements with peculiar frequency. I cannot accept this objection; but I will myself put into words something that sounds not unlike it. Among the thoughts that analysis brings to light are many which are relatively remote from the kernel of the dream and which look like artificial interpolations made for some particular purpose. That purpose is easy to divine. It is precisely *they* that constitute a connection, often a forced and far-fetched one, between the dream-content and the dream thoughts; and if these elements were weeded out of the analysis the result would often be that the component parts of the dream-content would be left not only without overdetermination but without any satisfactory determination at all. We shall be led to conclude that the multiple determination which decides what shall be included in a dream is not always a primary factor in dream-construction but is often the secondary product of a psychical force which is still unknown to us. Nevertheless multiple determination must be of importance in choosing what particular elements shall enter a dream, since we can see that a considerable expenditure of effort is used to bring it about in cases where it does not arise from the dream-material unassisted.

It thus seems plausible to suppose that in the dream-work a psychical force is operating which on the one hand strips the elements which have a high psychical value of their intensity, and on the other hand, *by means of overdetermination*, creates from elements of low psychical value new values, which afterwards find their way into the dream-content. If that is so, a *transference and displacement of psychical intensities* occurs in the process of dream-formation, and it is as a result of these that the difference between the text of the dream-content and that of the dream thoughts comes about. The process which we are here presuming is nothing less than the essential portion of the dream work; and it deserves to be described as 'dream-displacement.' Dream-displacement and dream-condensation are the two governing factors to whose activity we may in essence ascribe the form assumed by dreams.

Nor do I think we shall have any difficulty in recognizing the psychical force which manifests itself in the facts of dream-displacement. The consequence of the displacement is that the dream-content no longer resembles the core of the dream-thoughts and that the dream gives no more than a distortion of the dream-wish which exists in the unconscious. But we are already familiar with dream-distortion. We traced it back to the censorship which is exercised by one psychical agency in the mind over another. Dream-displacement is one of the chief methods by which that distortion is achieved. *Is fecit cui profuit*. We may assume, then, that dream-displacement comes about through the influence of the same censorship - that is, the censorship of endopsychic defence.¹

The question of the interplay of these factors - of displacement, condensation and overdetermination - in the construction of dreams, and the question which is a dominant factor and which a subordinate one - all of this we shall leave aside for later investigation. But we can state provisionally a second condition which must be satisfied by those elements of the dream-thoughts which make their way into the dream: *they must escape the censorship imposed by resistance*. And henceforward in interpreting dreams we shall take dream-displacement into account as an undeniable fact.

¹ [Footnote added 1909:] Since I may say that the kernel of my theory of dreams lies in my derivation of dream-distortion from the censorship, I will here insert the last part of a story from *Phantasien ein Realisten* by 'Lynkeus' (Vienna, 2nd edition, 1900), in which I have found this principal feature of my theory once more expounded.

'About a man who has the remarkable attribute of never dreaming nonsense . . .

"This splendid gift of yours, for dreaming as though you were waking, is a consequence of your virtue, of your kindness, your sense of justice, and your love of truth; it is the moral serenity of your nature which makes me understand all about you."

"But when I think the matter over properly," replied the other, "I almost believe that everyone is made like me, and that no one at all ever dreams nonsense. Any dream which one can remember clearly enough to describe it afterwards - any dream, that is to say, which is not a fever-dream - must *always* make sense, and it cannot possibly be otherwise. For things that were mutually contradictory could not group themselves into a single whole. The fact that time and space are often thrown into confusion does not affect the true content of the dream, since no doubt neither of them are of significance for its real essence. We often do the same thing in waking life. Only think of fairy tales and of the many daring products of the imagination, which are full of meaning and of which only a man without intelligence could say: 'This is nonsense, for it's impossible.'"

"If only one always knew how to interpret dreams in the right way, as you have just done with mine!" said his friend.

"That is certainly no easy task; but with a little attention on the part of the dreamer himself it should no doubt always succeed. -You ask why it is that for the most part it does *not* succeed? In you other people there seems always to be something that lies concealed in your dreams, something unchaste in a special and higher sense, a certain secret quality in your being which it is hard to follow. And that is why your dreams so often seem to be without meaning or even to be nonsense. But in the deepest sense this is not in the least so; indeed, it cannot be so at all - for it is always the same man, whether he is awake or dreaming."

(B)

THE MEANS OF REPRESENTATION IN DREAMS

In the process of transforming the latent thoughts into the manifest content of a dream we have found two factors at work: dream-condensation and dream-displacement. As we continue our investigation we shall, in addition to these, come across two further determinants which exercise an undoubted influence on the choice of the material which is to find access to the dream.

But first, even at the risk of appearing to bring our progress to a halt, I should like to take a preliminary glance at the processes involved in carrying out the interpretation of a dream. I cannot disguise from myself that the easiest way of making those processes clear and of defending their trustworthiness against criticism would be to take some particular dream as a sample, go through its interpretation (just as I have done with the dream of Irma's injection in my second chapter), and then collect the dream-thoughts which I have discovered and so on to reconstruct from them the process by which the dream was formed - in other words, to complete a dream-analysis by a dream-synthesis. I have in fact carried out that task for my own instruction on several specimens; but I cannot reproduce them here, since I am forbidden to do so for reasons connected with the nature of the psychical material involved - reasons which are of many kinds and which will be accepted as valid by any reasonable person. Such considerations interfered less in the *analysis* of dreams, since an analysis could be incomplete and nevertheless retain its value, even though it penetrated only a small way into the texture of the dream. But in the case of the *synthesis* of a dream I do not see how it can be convincing unless it is complete. I could only give a complete synthesis of dreams dreamt by people unknown to the reading public. Since, however, this condition is fulfilled only by my patients, who are neurotics, I must postpone this part of my exposition of the subject till I am able - in another volume - to carry the psychological elucidation of neuroses to a point at which it can make contact with our present topic.¹

¹ [Footnote added 1909:] Since writing the above words, I have published a complete analysis and synthesis of two dreams in my 'Fragment of the Analysis of a Case of Hysteria'. [Added 1914:] Otto Rank's analysis, 'Ein Traum, der sich selbst deutet', deserves mention as the most complete interpretation that has been published of a dream of considerable length.

My attempts at building up dreams by synthesis from the dream-thoughts have taught me that the material which emerges in the course of interpretation is not all of the same value. One part of it is made up of the essential dream-thoughts - those, that is, which completely replace the dream, and which, if there were no censorship of dreams, would be sufficient in themselves to replace it. The other part of the material is usually to be regarded as of less importance. Nor is it possible to support the view that all the thoughts of this second kind had a share in the formation of the dream. On the contrary, there may be associations among them which relate to events that occurred *after* the dream, between the times of dreaming and interpreting. This part of the material includes all the connecting paths that led from the manifest dream-content to the latent dream-thoughts, as well as the intermediate and linking associations by means of which, in the course of the process of interpretation, we came to discover these connecting paths.

We are here interested only in the essential dream-thoughts. These usually emerge as a complex of thoughts and memories of the of the most intricate possible structure, with all the attributes of the trains of thought familiar to us in waking life. They are not infrequently trains of thought starting out from more than one centre, though having points of contact. Each train of thought is almost invariably accompanied by its contradictory counterpart, linked with it by antithetical association.

The different portions of this complicated structure stand, of course, in the most manifold logical relations to one another. They can represent foreground and background, digressions and illustrations, conditions, chains of evidence and counter-arguments. When the whole mass of these dream-thoughts is brought under the pressure of the dream-work, and its elements are turned about, broken into fragments and jammed together - almost like pack-ice - the question arises of what happens to the logical connections which have hitherto formed its framework. What representation do dreams provide for 'if', 'because', 'just as', 'although', 'either-or', and all the other conjunctions without which we cannot understand sentences or speeches?

In the first resort our answer must be that dreams have no means at their disposal for representing these logical relations between the dream-thoughts. For the most part dreams disregard all these conjunctions, and it is only the substantive content of the dream-thoughts that they take over and manipulate. The restoration of the connections which the dream-work has destroyed is a task which has to be performed by the interpretative process.

The incapacity of dreams to express these things must lie in the nature of the psychical material out of which dreams are made. The plastic arts of painting and sculpture labour, indeed, under a similar limitation as compared with poetry, which can make use of speech; and here once again the reason for their incapacity lies in the nature of the material which these two forms of art manipulate in their effort to express something. Before painting became acquainted with the laws of expression by which it is governed, it made attempts to get over this handicap. In ancient paintings small labels were hung from the mouths of the persons represented, containing in written characters the speeches which the artist despaired of representing pictorially.

At this point an objection may perhaps be raised in dispute of the idea that dreams are unable to represent logical relations. For there are dreams in which the most complicated intellectual operations take place, statements are contradicted or confirmed, ridiculed or compared, just as they are in waking thought. But here again appearances are deceitful. If we go into the interpretation of dreams such as these, we find that the whole of this is *part of the material of the dream-thoughts and is not a representation of intellectual work performed during the dream itself*. What is reproduced by the ostensible thinking in the dream is the *subject-matter* of the dream-thoughts and not the *mutual relations between them*, the assertion of which constitutes thinking. I shall bring forward some instances of this. But the easiest point to establish in this connection is that all spoken sentences which occur in dreams and are specifically described as such are unmodified or slightly modified reproductions of speeches which are also to be found among the recollections in the material of the dream-thoughts. A speech of this kind is often no more than an allusion to some event included among the dream-thoughts, and the meaning of the dream may be a totally different one.

Nevertheless, I will not deny that critical thought-activity which is not a mere repetition of material in the dream-thoughts *does* have a share in the formation of dreams. I shall have to elucidate the part played by this factor at the end of the present discussion. It will then become apparent that this thought-activity is not produced by the dream-thoughts but by the dream itself after it has already, in a certain sense, been completed.

Provisionally, then, it may be said that the logical relations between the dream-thoughts are not given any separate representation in dreams. For instance, if a contradiction occurs in a dream, it is either a contradiction of the dream itself or a contradiction derived from the subject-matter of one of the dream-thoughts. A contradiction in a dream can only correspond in an exceedingly indirect manner to a contradiction *between* the dream-thoughts. But just as the art of painting eventually found a way of expressing, by means other than the floating labels, at least the *intention* of the words of the personages represented - affection, threats, warnings, and so on - so too there is a possible means by which dreams can take account of some of the logical relations between their dream-thoughts, by making an appropriate modification in the method of representation characteristic of dreams. Experience shows that different dreams vary greatly in this respect. While some dreams completely disregard the logical sequence of their material, others attempt to give as full an indication of it as possible. In doing so dreams depart sometimes more and some times less widely from the text that is at their disposal for manipulation. Incidentally dreams vary similarly in their treatment of the *chronological* sequence of the dream-thoughts, if such a sequence has been established in the unconscious (as, for instance, in the dream of Irma's injection).

What means does the dream-work possess for indicating these relations in the dream-thoughts which it is so hard to represent? I will attempt to enumerate them one by one.

In the first place, dreams take into account in a general way the connection which undeniably exists between all the portions of the dream-thoughts by combining the whole material into a single situation or event. They reproduce *logical connection* by *simultaneity in time*. Here they are acting like the painter who, in a picture of the School of Athens or of Parnassus, represents in one group all the philosophers or all the poets. It is true that they were never in fact assembled in a single hall or on a single mountain-top; but they certainly form a group in the conceptual sense.

Dreams carry this method of reproduction down to details. Whenever they show us two elements close together, this guarantees that there is some specially intimate connection between what correspond to them among the dream-thoughts. In the same way, in our system of writing, 'ab' means that the two letters are to be pronounced in a single syllable. If a gap is left between the 'a' and the 'b', it means that the 'a' is the last letter of one word and the 'b' is the first of the next one. So, too, collocations in dreams do not consist of any chance, disconnected portions of the dream-material, but of portions which are fairly closely connected in the dream-thoughts as well.

For representing *causal relations* dreams have two procedures which are in essence the same. Suppose the dream-thoughts run like this: 'Since this was so and so, such and such was bound to happen.' Then the commoner method of representation would be to introduce the dependent clause as an introductory dream and to add the principal clause as the main dream. If I have interpreted aright, the temporal sequence may be reversed. But the more extensive part of the dream always corresponds to the principal clause.

One of my women patients once produced an excellent instance of this way of representing causality in a dream which I shall later record fully. It consisted of a short prelude and a very diffuse piece of dream which was centred to a marked degree on a single theme and might be entitled 'The Language of Flowers.'

The introductory dream was as follows: *She went into the kitchen, where her two maids were, and found fault with them for not having got her 'bite of food' ready. At the same time she saw a very large quantity of common kitchen crockery standing upside down in the kitchen to drain; it was piled up in heaps. The two maids went to fetch some water and had to step into a kind of river which came right up to the house or into the yard.* The main dream then followed, beginning thus: *She was descending from a height over some strangely constructed palisades, and felt glad that her dress was not caught in them . . . etc.*

The introductory dream related to the dreamer's parents' home. No doubt she had often heard her mother using the words that occurred in the dream. The heaps of common crockery were derived from a modest hardware shop which was located in the same building. The other part of the dream contained a reference to her father, who used always to run after the maids and who eventually contracted a fatal illness during a flood. (The house stood near a river-bank.) Thus the thought concealed behind the introductory dream ran as follows: 'Because I was born in this house, in such mean and depressing circumstances . . . ' The main dream took up the same thought and presented it in a form modified by wish-fulfilment: 'I am of high descent.' Thus the actual underlying thought was: 'Because I am of such low descent, the course of my life has been so and so.'

The division of a dream into two unequal parts does not invariably, so far as I can see, signify that there is a causal relation between the thoughts behind the two parts. It often seems as though the same material were being represented in the two dreams from different points of view. (This is certainly the case where a series of dreams during one night end in an emission or orgasm - a series in which the somatic need finds its way to progressively clearer expression.) Or the two dreams may have sprung from separate centres in the dream-material, and their content may overlap, so that what is the centre in one dream is present as a mere hint in the other, and *vice versa*. But in a certain number of dreams a division into a shorter preliminary dream and a longer sequel does in fact signify that there is a causal relation between the two pieces.

The other method of representing a causal relation is adapted to less extensive material and consists in one image in the dream, whether of a person or thing, being transformed into another. The existence of a causal relation is only to be taken seriously if the transformation actually occurs before our eyes and not if we merely notice that one thing has appeared in the place of another.

I have said that the two methods of representing a causal relation were in essence the same. In both cases causation is represented by temporal sequence: in one instance by a sequence of dreams and in the other by the direct transformation of one image into another. In the great majority of cases, it must be confessed, the causal relation is not represented at all but is lost in the confusion of elements which inevitably occurs in the process of dreaming.

The alternative 'either-or' cannot be expressed in dreams in any way whatever. Both of the alternatives are usually inserted in the text of the dream as though they were equally valid. The dream of Irma's injection contains a classic instance of this. Its latent thoughts clearly ran: 'I am not responsible for the persistence of Irma's pains; the responsibility lies *either* in her recalcitrance to accepting my solution, *or* in the unfavourable sexual conditions under which she lives and which I cannot alter, *or* in the fact that her pains are not hysterical at all but of an organic nature.' The dream, on the other hand, fulfilled all of these possibilities (which were almost mutually exclusive), and did not hesitate to add a fourth solution, based on the dream-wish. After interpreting the dream, I proceeded to insert the 'either-or' into the context of the dream thoughts.

If, however, in reproducing a dream, its narrator feels inclined to make use of an 'either-or' - e.g. 'it was either a garden or a sitting-room' - what was present in the dream-thoughts was not an alternative but an 'and', a simple addition. An 'either-or' is mostly used to describe a dream-element that has a quality of vagueness - which, however, is capable of being resolved. In such cases the rule for interpretation is: treat the two apparent alternatives as of equal validity and link them together with an 'and'.

For instance, on one occasion a friend of mine was stopping in Italy and I had been without his address for a considerable time. I then had a dream of receiving a telegram containing this address. I saw it printed in blue on the telegraph form. The first word was vague:

'Via', perhaps
or 'Villa' ; the second was clear: 'Secerno'
or possibly even ('Casa')

The second word sounded like some Italian name and reminded me of discussions I had had with my friend on the subject of etymology. It also expressed my anger with him for having kept his address *secret* from me for so long. On the other hand, each of the three alternatives for the first word turned out on analysis to be an independent and equally valid starting point for a chain of thoughts.

During the night before my father's funeral I had a dream of a printed notice, placard or poster - rather like the notices forbidding one to smoke in railway waiting-rooms - on which appeared either

'You are requested to close the eyes'
or, 'You are requested to close an eye.'

I usually write this in the form:

the
'You are requested to close eye(s).'
an

Each of these two versions had a meaning of its own and led in a different direction when the dream was interpreted. I had chosen the simplest possible ritual for the funeral, for I knew my father's own views on such ceremonies. But some other members of the family were not sympathetic to such puritanical simplicity and thought we should be disgraced in the eyes of those who attended the funeral. Hence one of the versions: 'you are requested to close an eye', i.e. to 'wink at' or 'overlook.' Here it is particularly easy to see the meaning of the vagueness expressed by the 'either-or.' The dream-work failed to establish a unified wording for the dream-thoughts which could at the same time be ambiguous, and the two main lines of thought consequently began to diverge even in the manifest content of the dream.

In a few instances the difficulty of representing an alternative is got over by dividing the dream into two pieces of equal length.

The way in which dreams treat the category of contraries and contradictories is highly remarkable. It is simply disregarded. 'No' seems not to exist so far as dreams are concerned. They show a particular preference for combining contraries into a unity or for representing them as one and the same thing. Dreams feel themselves at liberty, moreover, to represent any element by its wishful contrary; so that there is no way of deciding at a first glance whether any element that admits of a contrary is present in the dream-thoughts as a positive or as a negative.¹

¹ [Footnote added 1911:] I was astonished to learn from a pamphlet by K. Abel, *The Antithetical Meaning of Primal Words* (1884) (cf. my review of it, 1910e) - and the fact has been confirmed by other philologists - that the most ancient languages behave exactly like dreams in this respect. In the first instance they have only a single word to describe the two contraries at the extreme ends of a series of qualities or activities (e.g. 'strong-weak', 'old-young', 'far-near', 'bind-sever'); they only form distinct terms for the two contraries by a secondary process of making small modifications in the common word. Abel demonstrates this particularly from Ancient Egyptian; but he shows that there are distinct traces of the same course of development in the Semitic and Indo-Germanic languages as well.

In one of the dreams recorded just above, the first clause of which has already been interpreted ('because my descent was such and such'), the dreamer saw herself climbing down over some palisades holding a blossoming branch in her hand. In connection with this image she thought of the angel holding a spray of lilies in pictures of the Annunciation - her own name was Maria - and of girls in white robes walking in Corpus Christi processions, when the streets are decorated with green branches. Thus the blossoming branch in the dream without any doubt alluded to sexual innocence. However, the branch was covered with *red* flowers, each of which was like a camellia. By the end of her walk - so the dream went on - the blossoms were already a good deal faded. There then followed some unmistakable allusions to menstruation. Accordingly, the same branch which was carried like a lily and as though by an innocent girl was at the same time an allusion to the *Dame aux camélias* who, as we know, usually wore a white camellia, except during her periods, when she wore a red one. The same blossoming branch (cf. 'des Mädchens Blüten' ['the maiden's blossoms'] in Goethe's poem 'Der Müllerin Verrat') represented both sexual innocence and its contrary. And the same dream which expressed her joy at having succeeded in passing through life immaculately gave one glimpses at certain points (e.g. in the fading of the blossoms) of the contrary train of ideas - of her having been guilty of various sins against sexual purity (in her childhood, that is). In analysing the dream it was possible clearly to distinguish the two trains of thought, of which the consoling one seemed the more superficial and the self-reproachful one the deeper-lying - trains of thought which were diametrically opposed to each other but whose similar though contrary elements were represented by the same elements in the manifest dream.

One and one only of these logical relations is very highly favoured by the mechanism of dream-formation; namely, the relation of similarity, consonance or approximation - the relation of 'just as'. This relation, unlike any other, is capable of being represented in dreams in a variety of ways.¹ Parallels or instances of 'just as' inherent in the material of the dream-thoughts constitute the first foundations for the construction of a dream; and no inconsiderable part of the dream-work consists in creating fresh parallels where those which are already present cannot find their way into the dream owing to the censorship imposed by resistance. The representation of the relation of similarity is assisted by the tendency of the dream-work towards condensation.

Similarity, consonance, the possession of common attributes - all these are represented in dreams by unification, which may either be present already in the material of the dream-thoughts or may be freshly constructed. The first of these possibilities may be described as 'identification' and the second as 'composition.' Identification is employed where *persons* are concerned; composition where *things* are the material of the unification. Nevertheless composition may also be applied to persons. Localities are often treated like persons.

In identification, only one of the persons who are linked by a common element succeeds in being represented in the manifest content of the dream, while the second or remaining persons seem to be suppressed in it. But this single covering figure appears in the dream in all the relations and situations which apply either to him or to the figures which he covers. In composition, where this is extended to persons, the dream-image contains features which are peculiar to one or other of the persons concerned but not common to them; so that the combination of these features leads to the appearance of a new unity, a composite figure. The actual process of composition can be carried out in various ways. On the one hand, the dream-figure may bear the name of one of the persons related to it - in which case we simply know directly, in a manner analogous to our waking knowledge, that this or that person is intended - while its visual features may belong to the other person. Or, on the other hand, the dream-image itself may be composed of visual features belonging in reality partly to the one person and partly to the other. Or again the second person's share in the dream-image may lie, not in its visual features, but in the gestures that we attribute to it, the words that we make it speak, or the situation in which we place it. In this last case the distinction between identification and the construction of a composite figure begins to lose its sharpness. But it may also happen that the formation of a composite figure of this kind is unsuccessful. If so, the scene in the dream is attributed to one of the persons concerned, while the other (and usually the more important one) appears as an attendant figure without any other function. The dreamer may describe the position in such a phrase as: 'My mother was there as well.' (Stekel.) An element of this kind in the dream-content may be compared to the 'determinatives' used in hieroglyphic script, which are not meant to be pronounced but serve merely to elucidate other signs.

¹ [Footnote added 1914:] Cf. Aristotle's remark on the qualifications of a dream-interpreter quoted above on p. 602 n. 2.

The common element which justifies, or rather causes, the combination of the two persons may be represented in the dream or may be omitted from it. As a rule the identification or construction of a composite person takes place for the very purpose of avoiding the representation of the common element. Instead of saying: 'A has hostile feelings towards me and so has B', I make a composite figure out of A and B in the dream, or I imagine A performing an act of some other kind which is characteristic of B. The dream-figure thus constructed appears in the dream in some quite new connection, and the circumstance that it represents both A and B justifies me in inserting at the appropriate point in the dream the element which is common to both of them, namely a hostile attitude towards me. It is often possible in this way to achieve quite a remarkable amount of condensation in the content of a dream; I can save myself the need for giving a direct representation of very complicated circumstances relating to one person, if I can find another person to whom some of these circumstances apply equally. It is easy to see, too, how well this method of representation by means of identification can serve to evade the censorship due to resistance, which imposes such severe conditions upon the dream-work. What the censorship objects to may lie precisely in certain ideas which, in the material of the dream-thoughts, are attached to a particular person; so I proceed to find a second person, who is also connected with the objectionable material, but only with part of it. The contact between the two persons upon this censorable point now justifies me in constructing a composite figure characterized by indifferent features derived from both. This figure, arrived at by identification or composition, is then admissible to the dream-content without censorship, and thus, by making use of dream-condensation, I have satisfied the claims of the dream-censorship.

When a common element between two persons is represented in a dream, it is usually a hint for us to look for another, concealed common element whose representation has been made impossible by the censorship. A displacement in regard to the common element has been made in order, as it were, to facilitate its representation. The fact that the composite figure appears in the dream with an indifferent common element leads us to conclude that there is another far from indifferent common element present in the dream-thoughts.

Accordingly, identification or the construction of composite figures serves various purposes in dreams: firstly to represent an element common to two persons, secondly to represent a *displaced* common element, and thirdly, too, to express a merely *wishful* common element. Since wishing that two persons had a common element frequently coincides with exchanging one for the other, this latter relation is also expressed in dreams by means of identification. In the dream of Irma's injection, I wished to exchange her for another patient: I wished, that is, that the other woman might be my patient just as Irma was. The dream took this wish into account by showing me a person who was called Irma, but who was examined in a position in which I had only had occasion to see the other woman. In the dream about my uncle an exchange of this kind became the central point of the dream: I identified myself with the Minister by treating and judging my colleagues no better than he did.

It is my experience, and one to which I have found no exception, that every dream deals with the dreamer himself. Dreams are completely egoistical.¹ Whenever my own ego does not appear in the content of the dream, but only some extraneous person, I may safely assume that my own ego lies concealed, by identification, behind this other person; I can insert my ego into the context. On other occasions, when my own ego does appear in the dream, the situation in which it occurs may teach me that some other person lies concealed, by identification behind my ego. In that case the dream should warn me to transfer on to myself, when I am interpreting the dream, the concealed common element attached to this other person. There are also dreams in which my ego appears along with other people who, when the identification is resolved, are revealed once again as my ego. These identifications should then make it possible for me to bring into contact with my ego certain ideas whose acceptance has been forbidden by the censorship. Thus my ego may be represented in a dream several times over, now directly and now through identification with extraneous persons. By means of a number of such identifications it becomes possible to condense an extraordinary amount of thought-material.² The fact that the dreamer's own ego appears several times, or in several forms, in a dream is at bottom no more remarkable than that the ego should be contained in a conscious thought several times or in different places or connections - e.g. in the sentence 'when I think what a healthy child I was'.

Identifications in the case of proper names of *localities* are resolved even more easily than in the case of persons, since here there is no interference by the ego, which occupies such a dominating place in dreams. In one of my dreams about Rome (see p. 680 f.), the place in which I found myself was called Rome, but I was astonished at the quantity of German posters at a street-corner. This latter point was a wish-fulfilment, which at once made me think of Prague; and the wish itself may perhaps have dated from a German-nationalist phase which I passed through during my youth, but have since got over. At the time at which I had the dream there was a prospect of my meeting my friend in Prague; so that the identification of Rome and Prague can be explained as a wishful common element: I would rather have met my friend in Rome than in Prague and I would have liked to exchange Prague for Rome for the purpose of this meeting.

¹ [Footnote added 1925:] Cf. the footnote on p. 746.

² When I am in doubt behind which of the figures appearing in the dream my ego is to be looked for, I observe the following rule: the person who in the dream feels an emotion which I myself experience in my sleep is the one who conceals my ego.

The possibility of creating composite structures stands foremost among the characteristics which so often lend dreams a fantastic appearance, for it introduces into the content of dreams elements which could never have been objects of actual perception. The psychical process of constructing composite images in dreams is evidently the same as when we imagine or portray a centaur or a dragon in waking life. The only difference is that what determines the production of the imaginary figure in waking life is the impression which the new structure itself is intended to make; whereas the formation of the composite structure in a dream is determined by a factor extraneous to its actual shape - namely the common element in the dream-thoughts. Composite structures in dreams can be formed in a great variety of ways. The most naïve of these procedures merely represents the attributes of one thing to the accompaniment of a knowledge that they also belong to something else. A more painstaking technique combines the features of both objects into a new image and in so doing makes clever use of any similarities that the two objects may happen to possess in reality. The new structure may seem entirely absurd or may strike us as an imaginative success, according to the material and to the ingenuity with which it is put together. If the objects which are to be condensed into a single unity are much too incongruous, the dream-work is often content with creating a composite structure with a comparatively distinct nucleus, accompanied by a number of less distinct features. In that case the process of unification into a single image may be said to have failed. The two representations are superimposed and produce something in the nature of a contest between the two visual images. One might arrive at similar representations in a drawing, if one tried to illustrate the way in which a general concept is formed from a number of individual perceptual images.

Dreams are, of course, a mass of these composite structures. I have given some examples of them in dreams that I have already analysed; and I will now add a few more. In the dream reported below on p. 816 ff., which describes the course of the patient's life 'in the language of flowers' the dream-ego held a blossoming branch in her hand which, as we have seen, stood both for innocence and for sexual sinfulness. The branch, owing to the way in which the blossoms were placed on it, also reminded the dreamer of *cherry*-blossom; the blossoms themselves, regarded individually, were *camellias*, and moreover the general impression was of an *exotic* growth. The common factor among the elements of this composite structure was shown by the dream-thoughts. The blossoming branch was composed of allusions to gifts made to her in order to win, or attempt to win, her favour. Thus she had been given *cherries* in her childhood and, later in life, a *camellia*-plant; while '*exotic*' was an allusion to a much-travelled naturalist who had tried to win her favour with a flower-drawing. - Another of my women patients produced in one of her dreams a thing that was intermediate between a bathing-hut at the seaside, an outside closet in the country and an attic in a town house. The first two elements have in common a connection with people naked and undressed; and their combination with the third element leads to the conclusion that (in her childhood) an attic had also been a scene of undressing. - Another dreamer, a man, produced a composite locality out of two places where 'treatments' are carried out: one of them being my consulting-room and the other the place of entertainment where he had first made his wife's acquaintance. - A girl dreamt, after her elder brother had promised to give her a feast of caviare, that this same brother's legs were *covered all over with black grains of caviare*. The element of '*contagion*' (in the moral sense) and a recollection of a *rash* in her childhood, which had covered her legs all over with *red* spots, instead of black ones, had been combined with the *grains of caviare* into a new concept - namely the concept of '*what she had got from her brother*.' In this dream, as in others, parts of the human body were treated like objects. - In a dream recorded by Ferenczi, a composite image occurred was made up from the figure of a *doctor* and of a *horse* and was also dressed in a *nightshirt*. The element common to these three components was arrived at in the analysis after the woman-patient had recognized that the night-shirt was an allusion to her father in a scene from her childhood. In all three cases it was a question of an object of her sexual curiosity. When she was a child she had often been taken by her nurse to a military stud-farm where she had ample opportunities of gratifying what was at that time her still uninhibited curiosity.

I have asserted above that dreams have no means of expressing the relation of a contradiction, a contrary or a 'no'. I shall now proceed to give a first denial of this assertion. One class of cases which can be comprised under the heading of 'contraries' are, as we have seen, simply represented by identification - cases, that is, in which the idea of an exchange or substitution can be brought into connection with the contrast. I have given a number of instances of this. Another class of contraries in the dream-thoughts, falling into a category which may be described as 'contrariwise' or 'just the reverse', find their way into dreams in the following remarkable fashion, which almost deserves to be described as a joke. The 'just the reverse' is not itself represented in the dream-content, but reveals its presence in the material through the fact that some piece of the dream-content, which has already been constructed and happens (for some other reason) to be adjacent to it, is - as it were by an afterthought - turned round the other way. The process is more easily illustrated than described. In the interesting 'Up and Down' dream (p. 759 ff.) the representation of the climbing in the dream was the reverse of what it was in its prototype in the dream-thoughts - that is, in the introductory scene from Daudet's *Sappho*: in the dream the climbing was difficult at first but easier later, while in the Daudet scene it was easy at first but more and more difficult later. Further, the 'up above' and 'down below' in the dreamer's relation to his brother were represented the other way round in the dream. This pointed to the presence of a reversed or contrary relation between two pieces of the material in the dream-thoughts; and we found it in the dreamer's childhood phantasy of being carried by his wet-nurse, which was the reverse of the situation in the novel, where the hero was carrying his mistress. So too in my dream of Goethe's attack on Herr M. (see below, p. 886 ff.) there is a similar 'just the reverse' which has to be put straight before the dream can be successfully interpreted. In the dream Goethe made an attack on a young man, Herr M.; in the real situation contained in the dream-thoughts a man of importance, my friend, had been attacked by an unknown young writer. In the dream I based a calculation on the date of Goethe's death; in reality the calculation had been made from the year of the paralytic patient's birth. The thought which turned out to be the decisive one in the dream-thoughts was a contradiction of the idea that Goethe should be treated as though he were a lunatic. 'Just the reverse', said the dream, 'if you don't understand the book, it's *you* that are feeble-minded, and not the author.' I think, moreover, that all these dreams of turning things round the other way include a reference to the contemptuous implications of the idea of 'turning one's back on something.' (E.g. the dreamer's turning round in relation to his brother in the *Sappho* dream.) It is remarkable to observe, moreover, how frequently reversal is employed precisely in dreams arising from repressed homosexual impulses.

Incidentally, reversal, or turning a thing into its opposite, is one of the means of representation most favoured by the dream-work and one which is capable of employment in the most diverse directions. It serves in the first place to give expression to the fulfilment of a wish in reference to some particular element of the dream-thoughts. 'If only it had been the other way round!' This is often the best way of expressing the ego's reaction to a disagreeable fragment of memory. Again, reversal is of quite special use as a help to the censorship, for it produces a mass of distortion in the material which is to be represented, and this has a positively paralysing effect, to begin with, on any attempt at understanding the dream. For that reason, if a dream obstinately declines to reveal its meaning, it is always worth while to see the effect of reversing some particular elements in its manifest content, after which the whole situation often becomes immediately clear.

And, apart from the reversal of subject-matter, *chronological* reversal must not be overlooked. Quite a common technique of dream-distortion consists in representing the outcome of an event or the conclusion of a train of thought at the beginning of a dream and of placing at its end the premises on which the conclusion was based or the causes which led to the event. Anyone who fails to bear in mind this technical method adopted by dream-distortion will be quite at a loss when confronted with the task of interpreting a dream.¹

In some instances, indeed, it is only possible to arrive at the meaning of a dream after one has carried out quite a number of reversals of its content in various respects. For instance, in the case of a young obsessional neurotic, there lay concealed behind one of his dreams the memory of a death-wish dating from his childhood and directed against his father, of whom he had been afraid. Here is the text of the dream: *His father was scolding him for coming home so late*. The context in which the dream occurred in the psycho-analytic treatment and the dreamer's associations showed, however, that the original wording must have been that *he* was angry with his *father*, and that in his view his father always came home too *early* (i.e. too soon). He would have preferred it if his father had not come home *at all*, and this was the same thing as a death-wish against his father. (See p. 733 f.) For as a small boy, during his father's temporary absence, he had been guilty of an act of sexual aggression against someone, and as a punishment had been threatened in these words: 'Just you wait till your father comes back!'

¹ [Footnote added 1909:] Hysterical attacks sometimes make use of the same kind of chronological reversal in order to disguise their meaning from observers. For instance, a hysterical girl needed to represent something in the nature of a brief romance in one of her attacks - a romance of which she had had a phantasy in her unconscious after an encounter with someone on the suburban railway. She imagined how the man had been attracted by the beauty of her foot and had spoken to her while she was reading; whereupon she had gone off with him and had had a passionate love-scene. Her attack *began* with a representation of this love-scene by convulsive twitching of her body, accompanied by movements of her lips to represent kissing and tightening of her arms to represent embracing. She then hurried into the next room, sat down on a chair, raised her skirt so as to show her foot, pretended to be reading a book and spoke to me (that is, answered me). - [Added 1914:] Cf. in this connection what Artemidorus says: 'In interpreting the images seen in dreams one must sometimes follow them from the beginning to the end and sometimes from the end to the beginning . . .'

If we wish to pursue our study of the relations between dream-content and dream-thoughts further, the best plan will be to take dreams themselves as our point of departure and consider what certain *formal* characteristics of the method of representation in dreams signify in relation to the thoughts underlying them. Most prominent among these formal characteristics, which cannot fail to impress us in dreams, are the differences in sensory intensity between particular dream-images and in the distinctness of particular parts of dreams or of whole dreams as compared with one another.

The differences in intensity between particular dream-images cover the whole range extending between a sharpness of definition which we feel inclined, no doubt unjustifiably, to regard as greater than that of reality and an irritating vagueness which we declare characteristic of dreams because it is not completely comparable to any degree of indistinctness which we ever perceive in real objects. Furthermore we usually describe an impression which we have of an indistinct object in a dream as 'fleeting', while we feel that those dream-images which are more distinct have been perceived for a considerable length of time. The question now arises what it is in the material of the dream-thoughts that determines these differences in the vividness of particular pieces of the content of a dream.

We must begin by countering certain expectations which almost inevitably present themselves. Since the material of a dream may include real sensations experienced during sleep, it will probably be presumed that these, or the elements in the dream derived from them, are given prominence in the dream content by appearing with special intensity; or, conversely, that whatever is very specially vivid in a dream can be traced back to real sensations during sleep. In my experience, however, this has never been confirmed. It is not the case that the elements of a dream which are derivatives of real impressions during sleep (i.e. of nervous stimuli) are distinguished by their vividness from other elements which arise from memories. The factor of reality counts for nothing in determining the intensity of dream images.

Again, it might be expected that the *sensory* intensity (that is, the vividness) of particular dream-images would be related to the *psychical* intensity of the elements in the dream-thoughts corresponding to them. In the latter, psychical intensity coincides with psychical *value*: the most intense elements are also the most important ones - those which form the centre-point of the dream-thoughts. We know, it is true, that these are precisely elements which, on account of the censorship, cannot as a rule make their way into the content of the dream; nevertheless, it might well be that their immediate derivatives which represent them in the dream might bear a higher degree of intensity, without necessarily on that account forming the centre of the dream. But this expectation too is disappointed by a comparative study of dreams and the material from which they are derived. The intensity of the elements in the one has no relation to the intensity of the elements in the other: the fact is that a complete 'transvaluation of all psychical values' takes place between the material of the dream-thoughts and the dream. A direct derivative of what occupies a dominating position in the dream-thoughts can often only be discovered precisely in some transitory element of the dream which is quite overshadowed by more powerful images.

The intensity of the elements of a dream turns out to be determined otherwise - and by two independent factors. In the first place, it is easy to see that the elements by which the wish-fulfilment is expressed are represented with special intensity. And in the second place, analysis shows that the most vivid elements of a dream are the starting-point of the most numerous trains of thought - that the most vivid elements are also those with the most numerous determinants. We shall not be altering the sense of this empirically based assertion if we put it in these terms: the greatest intensity is shown by those elements of a dream on whose formation the greatest amount of condensation has been expended. We may expect that it will eventually turn out to be possible to express this determinant and the other (namely relation to the wish-fulfilment) in a single formula.

The problem with which I have just dealt - the causes of the greater or less intensity or clarity of particular elements of a dream - is not to be confounded with another problem, which relates to the varying clarity of whole dreams or sections of dreams. In the former case clarity is contrasted with vagueness, but in the latter case it is contrasted with confusion. Nevertheless it cannot be doubted that the increase and decrease of the qualities in the two scales run parallel. A section of a dream which strikes us as perspicuous usually contains intense elements; a dream which is obscure, on the other hand, is composed of elements of small intensity. Yet the problem presented by the scale which runs from what is apparently clear to what is obscure and confused is far more complicated than that of the varying degrees of vividness of dream-elements. Indeed, for reasons which will appear later, the former problem cannot yet be discussed.

In a few cases we find to our surprise that the impression of clarity or indistinctness given by a dream has no connection at all with the make-up of the dream itself but arises from the material of the dream-thoughts and is a constituent of it. Thus I remember a dream of mine which struck me when I woke up as being so particularly well-constructed, flawless and clear that, while I was still half-dazed with sleep, I thought of introducing a new category of dreams which were not subject to the mechanisms of condensation and displacement but were to be described as 'phantasies during sleep.' Closer examination proved that this rarity among dreams showed the same gaps and flaws in its structure as any other; and for that reason I dropped the category of 'dream-phantasies.'¹ The content of the dream, when it was arrived at, represented me as laying before my friend a difficult and long-sought theory of bisexuality; and the wish-fulfilling power of the dream was responsible for our regarding this theory (which, incidentally, was not given in the dream) as clear and flawless. Thus what I had taken to be a judgement on the completed dream was actually a part, and indeed the essential part, of the dream-content. The dream-work had in this case encroached, as it were, upon my first waking thoughts and had conveyed to me as a *judgement* upon the dream the part of the material of the dream-thoughts which it had not succeeded in representing accurately in the dream. I once came across a precise counterpart to this in a woman patient's dream during analysis. To begin with she refused altogether to tell it me, 'because it was so indistinct and muddled'. At length, protesting repeatedly that she felt no certainty that her account was correct, she informed me that several people had come into the dream - she herself, her husband and her father - and that it was as though she had not known whether her husband was her father, or who her father was, or something of that sort. This dream, taken in conjunction with her associations during the analytic session, showed beyond a doubt that it was a question of the somewhat commonplace story of a servant-girl who was obliged to confess that she was expecting a baby but was in doubts as to 'who the (baby's) father really was'.² Thus here again the lack of clarity shown by the dream was a part of the material which instigated the dream: part of this material, that is, was represented in the *form* of the dream. *The form of a dream, or the form in which it is dreamt is used with quite surprising frequency for representing its concealed subject-matter.*

¹ [Footnote added 1930:] Whether rightly I am now uncertain.

² Her accompanying hysterical symptoms were amenorrhoea and great depression (which was this patient's chief symptom).

Glosses on a dream, or apparently innocent comments on it, often serve to disguise a portion of what has been dreamt in the subtlest fashion, though in fact betraying it. For instance, a dreamer remarked that at one point 'the dream had been wiped away'; and the analysis led to an infantile recollection of his listening to someone wiping himself after defaecating. Or here is another example which deserves to be recorded in detail. A young man had a very clear dream which reminded him of some phantasies of his boyhood that had remained conscious. He dreamt that it was evening and that he was in a hotel at a summer resort. He mistook the number of his room and went into one in which an elderly lady and her two daughters were undressing and going to bed. He proceeded: 'Here there are some gaps in the dream; there's something missing. Finally there was a man in the room who tried to throw me out, and I had to have a struggle with him.' He made vain endeavours to recall the gist and drift of the boyish phantasy to which the dream was evidently alluding; until at last the truth emerged that what he was in search of was already in his possession in his remark about the obscure part of the dream. The 'gaps' were the genital apertures of the women who were going to bed; and 'there's something missing' described the principal feature of the female genitalia. When he was young he had had a consuming curiosity to see a woman's genitals and had been inclined to hold to the infantile sexual theory according to which women have male organs.

An analogous recollection of another dreamer assumed a very similar shape. He dreamt as follows: *'I was going into the Volkgarten Restaurant with Fräulein K. . . . then came an obscure patch, an interruption . . . , then I found myself in the salon of a brothel, where I saw two or three women, one of them in her chemise and drawers.'*

ANALYSIS. - Fräulein K. was the daughter of his former chief, and, as he himself admitted, a substitute sister of his own. He had seldom had an opportunity of talking to her, but they once had a conversation in which 'it was just as though we had become aware of our sex, it was as though I were to say: "I'm a man and you're a woman."' He had only once been inside the restaurant in question, with his brother-in-law's sister, a girl who meant nothing at all to him. Another time he had gone with a group of three ladies as far as the entrance of the same restaurant. These ladies were his sister, his sister-in-law and the brother-in-law's sister who has just been mentioned. All of them were highly indifferent to him, but all three fell into the class of 'sister.' He had only seldom visited a brothel - only two or three times in his life.

The interpretation was based on the 'obscure patch' and the 'interruption' in the dream, and put forward the view that in his boyish curiosity he had occasionally, though only seldom, inspected the genitals of a sister who was a few years his junior. Some days later he had a conscious recollection of the misdeed alluded to by the dream.

The content of all dreams that occur during the same night forms part of the same whole; the fact of their being divided into several sections, as well as the grouping and number of those sections - all of this has a meaning and may be regarded as a piece of information arising from the latent dream-thoughts. In interpreting dreams consisting of several main sections or, in general, dreams occurring during the same night, the possibility should not be overlooked that separate and successive dreams of this kind may have the same meaning, and may be giving expression to the same impulses in different material. If so, the first of these homologous dreams to occur is often the more distorted and timid, while the succeeding one will be more confident and distinct.

Pharaoh's dreams in the Bible of the kine and the ears of corn, which were interpreted by Joseph, were of this kind. They are reported more fully by Josephus (*Ancient History of the Jews*, Book 2, Chapter 5) than in the Bible. After the King had related his first dream, he said: 'After I had seen this vision, I awaked out of my sleep; and, being in disorder, and considering with myself what this appearance should be, I fell asleep again, and saw another dream, more wonderful than the foregoing, which did more affright and disturb me . . .' After hearing the King's account of the dream, Joseph replied: 'This dream, O King, although seen under two forms, signifies one and the same event . . .'

In his 'Contribution to the Psychology of Rumour', Jung (1910*b*) describes how the disguised erotic dream of a school-girl was understood by her school-friends without any interpreting and how it was further elaborated and modified. He remarks in connection with one of these dream stories: 'The final thought in a long series of dream-images contains precisely what the first image in the series had attempted to portray. The censorship keeps the complex at a distance as long as possible by a succession of fresh symbolic screens, displacements, innocent disguises, etc.' (Ibid., 87.) Scherner (1861, 166) was well acquainted with this peculiarity of the method of representation in dreams and describes it, in connection with his theory of organic stimuli, as a special law: 'Lastly, however, in all symbolic dream-structures which arise from particular nervous stimuli, the imagination observes a general law: at the beginning of a dream it depicts the object from which the stimulus arises only by the remotest and most inexact allusions, but at the end, when the pictorial effusion has exhausted itself, it nakedly presents the stimulus itself, or, as the case may be, the organ concerned or the function of that organ, and therewith the dream, having designated its actual organic cause, achieves its end . . .'

Otto Rank (1910) has produced a neat confirmation of this law of Scherner's. A girl's dream reported by him was composed of two separate dreams dreamt, with an interval between them, during the same night, the second of which ended with an orgasm. It was possible to carry out a detailed interpretation of this second dream even without many contributions from the dreamer; and the number of connections between the contents of the two dreams made it possible to see that the first dream represented in a more timid fashion the same thing as the second. So that the second, the dream with the orgasm, helped towards the complete explanation of the first. Rank rightly bases upon this example a discussion of the general significance of dreams of orgasm or emission for the theory of dreaming.

Nevertheless in my experience it is only rarely that one is in a position to interpret the clarity or confusion of a dream by the presence of certainty or doubt in its material. Later on I shall have to disclose a factor in dream-formation which I have not yet mentioned and which exercises the determining influence upon the scale of these qualities in any particular dream.

Sometimes, in a dream in which the same situation and setting have persisted for some time, an interruption will occur which is described in these words: 'But then it was as though at the same time it was another place, and there such and such a thing happened.' After a while the main thread of the dream may be resumed, and what interrupted it turns out to be a subordinate clause in the dream-material - an interpolated thought. A conditional in the dream-thoughts has been represented in the dream by simultaneity: 'if' has become 'when'.

What is the meaning of the sensation of inhibited movement which appears so commonly in dreams and verges so closely upon anxiety? One tries to move forward but finds oneself glued to the spot, or one tries to reach something but is held up by a series of obstacles. A train is on the point of departure but one is unable to catch it. One raises one's hand to avenge an insult but finds it powerless and so forth. We have already met with this sensation in dreams of exhibiting, but have not as yet made any serious attempt to interpret it. An easy but insufficient answer would be to say that motor paralysis prevails in sleep and that we become aware of it in the sensation we are discussing. But it may be asked why in that case we are not perpetually dreaming of these inhibited movements; and it is reasonable to suppose that this sensation, though one which can be summoned up at any moment during sleep, serves to facilitate some particular kind of representation, and is only aroused when the material of the dream-thoughts needs to be represented in that way.

This 'not being able to do anything' does not always appear in dreams as a sensation but is sometimes simply a part of the content of the dream. A case of this sort seems to me particularly well qualified to throw light on the meaning of this feature of dreaming. Here is an abridged version of a dream in which I was apparently charged with dishonesty. *The place was a mixture of a private sanatorium and several other institutions. A man-servant appeared to summon me to an examination. I knew in the dream that something had been missed and that the examination was due to a suspicion that I had appropriated the missing article. (The analysis showed that the examination was to be taken in two senses and included a medical examination.) Conscious of my innocence and of the fact that I held the position of a consultant in the establishment, I accompanied the servant quietly. At the door we were met by another servant who said, pointing to me: 'Why have you brought him? He's a respectable person.'* I then went, unattended, into a large hall, with machines standing in it, which reminded me of an Inferno with its hellish instruments of punishment. *Stretched out on one apparatus I saw one of my colleagues, who had every reason to take some notice of me; but he paid no attention. I was then told I could go. But I could not find my hat and could not go after all.*

The wish-fulfilment of the dream evidently lay in my being recognized as an honest man and told I could go. There must therefore have been all kinds of material in the dream-thoughts containing a contradiction of this. That I could go was a sign of my absolution. If therefore something happened at the end of the dream which prevented my going, it seems plausible to suppose that the suppressed material containing the contradiction was making itself felt at that point. My not being able to find my hat meant accordingly: 'After all you're *not* an honest man.' Thus the 'not being able to do something' in this dream was a way of expressing a contradiction - a 'no' - so that my earlier statement that dreams cannot express a 'no' requires correction.¹

In other dreams, in which the 'not carrying out' of a movement occurs as a *sensation* and not simply as a *situation*, the sensation of the inhibition of a movement gives a more forcible expression to the same contradiction - it expresses a volition which is opposed by a counter-volition. Thus the sensation of the inhibition of a movement represents a *conflict of will*. We shall learn later that the motor paralysis accompanying sleep is precisely one of the fundamental determinants of the psychical process during dreaming. Now an impulse transmitted along the motor paths is nothing other than a volition, and the fact of our being so certain that we shall feel that impulse inhibited during sleep is what makes the whole process so admirably suited for representing an act of volition and a 'no' which opposes it. It is also easy to see, on my explanation of anxiety, why the sensation of an inhibition of will approximates so closely to anxiety and is so often linked with it in dreams. Anxiety is a libidinal impulse which has its origin in the unconscious and is inhibited by the preconscious.² When, therefore, the sensation of inhibition is linked with anxiety in a dream, it must be a question of an act of volition which was at one time capable of generating libido - that is, it must be a question of a sexual impulse.

¹ In the complete analysis there was a reference to an event in my childhood, reached by the following chain of association. 'Der Mohr hat seine Schuldigkeit getan, der Mohr *kahn gehen*.' ['The Moor has done his duty, the Moor *can go*.'] Then came a facetious conundrum: 'How old was the Moor when he had done his duty?' - 'One year old, because then he could go [*gehen*] - both 'to go' and 'to walk': (It appears that I came into the world with such a tangle of black hair that my young mother declared I was a little Moor.) - My not being able to find my hat was an occurrence from waking life which was used in more than one sense. Our housemaid, who was a genius at putting things away, had hidden it. -The end of this dream also concealed a rejection of some melancholy thoughts about death: 'I am far from having done my duty, so I must not go yet.' - Birth and death were dealt with in it, just as they had been in the dream of Goethe and the paralytic patient, which I had dreamt a short time before. (See pp. 797, 886 ff.)

² [*Footnote added 1930:*] In the light of later knowledge this statement can no longer stand.

I shall deal elsewhere (see below) with the meaning and psychical significance of the judgement which often turns up in dreams expressed in the phrase 'after all this is only a dream'. Here I will merely say in anticipation that it is intended to detract from the importance of what is being dreamt. The interesting and allied problem, as to what is meant when some of the content of a dream is described in the dream itself as 'dreamt' - the enigma of the 'dream within a dream' - has been solved in a similar sense by Stekel, who has analysed some convincing examples. The intention is, once again, to detract from the importance of what is 'dreamt' in the dream, to rob it of its reality. What is dreamt in a dream after waking from the 'dream within a dream' is what the dream-wish seeks to put in the place of an obliterated reality. It is safe to suppose, therefore, that what has been 'dreamt' in the dream is a representation of the reality, the true recollection, while the continuation of the dream, on the contrary, merely represents what the dreamer wishes. To include something in a 'dream within a dream' is thus equivalent to wishing that the thing described as a dream had never happened. In other words, if a particular event is inserted into a dream as a dream by the dream-work itself, this implies the most decided confirmation of the reality of the event - the strongest *affirmation* of it. The dream-work makes use of dreaming as a form of repudiation, and so confirms the discovery that dreams are wish-fulfilments.

(D)

CONSIDERATIONS OF REPRESENTABILITY

We have been occupied so far with investigating the means by which dreams represent the relations between the dream-thoughts. In the course of this investigation, however, we have more than once touched upon the further topic of the general nature of the modifications which the material of the dream-thoughts undergoes for the purpose of the formation of a dream. We have learnt that that material, stripped to a large extent of its relations, is submitted to a process of compression, while at the same time displacements of intensity between its elements necessarily bring about a psychical transvaluation of the material. The displacements we have hitherto considered turned out to consist in the replacing of some one particular idea by another in some way closely associated with it, and they were used to facilitate condensation in so far as, by their means, instead of *two* elements, a single common element intermediate between them found its way into the dream. We have not yet referred to any other sort of displacement. Analyses show us, however, that another sort exists and that it reveals itself in a change in the *verbal expression* of the thoughts concerned. In both cases there is a displacement along a chain of associations; but a process of such a kind can occur in various psychical spheres, and the outcome of the displacement may in one case be that one element is replaced by another, while the outcome in another case may be that a single element has its *verbal form* replaced by another.
